A landmark result in the study of logics for formal verification is Janin & Walukiewicz’s theorem, stating that the modal μ -calculus (μ ML) is equivalent modulo bisimilarity to standard monadic second-order logic (here abbreviated as SMSO), over the class of labelled transition systems (LTSs for short). Our work proves two results of the same kind, one for the alternation-free or *noetherian* fragment μ_N ML of μ ML on the modal side, and one for WMSO, weak monadic second-order logic, on the second-order side. In the setting of binary trees, with explicit functions accessing the left- and right successor of a node, it was known that WMSO is equivalent to the appropriate version of alternation-free μ -calculus. Our analysis shows that the picture changes radically once we consider, as Janin & Walukiewicz did, the standard modal μ -calculus, interpreted over arbitrary LTSs.

The first theorem that we prove is that, over LTSs, μ_N ML is equivalent modulo bisimilarity to *noetherian* MSO (NMSO), a newly introduced variant of SMSO where second-order quantification ranges over “conversely well-founded” subsets only. Our second theorem starts from WMSO, and proves it equivalent modulo bisimilarity to a fragment of μ_N ML defined by a notion of continuity. Analogously to Janin & Walukiewicz’s result, our proofs are automata-theoretic in nature: as another contribution, we introduce classes of parity automata characterising the expressiveness of WMSO and NMSO (on tree models) and of μ_C ML and μ_N ML (for all transition systems).

1. INTRODUCTION

1.1. Expressiveness modulo bisimilarity

A seminal result in the theory of modal logic is van Benthem's Characterisation Theorem [van Benthem 1977], stating that, over the class of all labelled transition systems (LTSs for short), every bisimulation-invariant first-order formula is equivalent to (the standard translation of) a modal formula:

$$\text{ML} \equiv \text{FO} / \leftrightarrow \quad (\text{over the class of all LTSs}). \quad (1)$$

Over the years, a wealth of variations of the Characterisation Theorem have been obtained. For instance, van Benthem's theorem is one of the few preservation results that transfers to the setting of finite models [Rosen 1997]; for a recent, rich source of van Benthem-style characterisation results, see [Dawar and Otto 2009]. The general pattern of these results takes the shape

$$M \equiv L / \leftrightarrow \quad (\text{over a class of models } C). \quad (2)$$

Apart from their obvious relevance to model theory, the interest in these results increases if C consists of transition structures that represent certain computational processes, as in the theory of the formal specification and verification of properties of software. In this context, one often takes the point of view that bisimilar models represent *the same* process. For this reason, only bisimulation-invariant properties are relevant. Seen in this light, (2) is an *expressive completeness* result: all the relevant properties expressible in L (which is generally some rich yardstick formalism), can already be expressed in a (usually computationally more feasible) modal fragment M .

Of special interest to us is the work [Janin and Walukiewicz 1996], which extends van Benthem's result to the setting of *second-order* logic, by proving that the bisimulation-invariant fragment of standard monadic second-order logic (MSO) is the *modal μ -calculus* (μML), viz., the extension of basic modal logic with least- and greatest fixpoint operators:

$$\mu\text{ML} \equiv \text{MSO} / \leftrightarrow \quad (\text{over the class of all LTSs}). \quad (3)$$

The aim of this paper is to study the fine structure of such connections between second-order logics and modal μ -calculi, obtaining variations of the expressiveness completeness results (1) and (3).

Our departure point is a result from [Arnold and Niwinski 1992] for the class of *binary* trees. Their setting is somewhat different from ours; in particular, since their trees have explicit functions accessing the left- and right successor of a node, the notion of bisimilarity trivialises to the isomorphism relation. Nevertheless, the key observation of Arnold & Niwiński is to link the *alternation-free fragment* of a modal μ -calculus to so-called *weak* MSO, the version of monadic second-order logic where second-order quantification is restricted to finite sets. Here, the alternation-free constraint means that only trivial interactions between least- and greatest fixpoint operators are permitted (more precise definitions will be provided in Section 3).

On the basis of the results by Janin & Walukiewicz and by Arnold & Niwiński it is natural to conjecture that

$$\mu_N\text{ML} \equiv \text{WMSO} / \leftrightarrow \quad (\text{over the class of finitely branching trees}), \quad (4)$$

where a tree is said to be *finitely branching* if each node has only finitely many immediate successors, and the logic $\mu_N\text{ML}$ is the alternation-free fragment of μML , or, as we shall explain further on, the 'noetherian' version of the modal μ -calculus. Note that this logic $\mu_N\text{ML}$ is a very natural fragment of the full μ -calculus; in particular, since the alternation depth of a fixpoint formula is one of the key parameters that determine the complexity of model checking algorithms for μML [Calude et al. 2017], the

alternation-free fragment is of special interest for applications. Similarly, *weak* MSO, the logic featuring on the right-hand side of (4), is a well-known variation of standard MSO, and it also has been studied in the setting of applications in software verification (see e.g. [Grädel et al. 2002, Ch. 3]).

In other words, (4) is an interesting expressive completeness statement, linking two well-known logical systems. Nevertheless, while we will show that (4) holds indeed, our investigations take a wider scope. Note that (4) only offers a comparison of the logics $\mu_N\text{ML}$ and WMSO on finitely branching trees, whereas (1) and (3) work at the level of arbitrary models. In fact, it turns out that the picture in the more general setting is far more subtle. First of all, we know that already at the level of arbitrary trees, the equation $\mu_N\text{ML} \equiv \text{WMSO}/\leftrightarrow$ is *false*, since the class of conversely well-founded trees, definable by the formula $\mu x. \Box x$ of $\mu_N\text{ML}$, is not WMSO-definable. Moreover, whereas WMSO is a fragment of SMSO on finitely branching trees, as soon as we allow for infinite branching the two logics turn out to have *incomparable* expressive power — we will discuss the details in Section 3.

One of the main questions of this work, then, is to clarify the relation between $\text{WMSO}/\leftrightarrow$ and $\mu_N\text{ML}$ on arbitrary LTSs. We shall prove that, in this more general setting, the equation (4) “splits” into the following two results, which refer to a relatively unknown fragment $\mu_C\text{ML}$ of the modal μ -calculus, and introduce a new second-order logic NMSO.

THEOREM 1.1.

$$\mu_C\text{ML} \equiv \text{WMSO}/\leftrightarrow \quad (\text{over the class of all LTSs}). \quad (5)$$

$$\mu_N\text{ML} \equiv \text{NMSO}/\leftrightarrow \quad (\text{over the class of all LTSs}). \quad (6)$$

For the first result (5), our strategy is to start from WMSO and seek a suitable modal fixpoint logic characterising its bisimulation-invariant fragment. Second-order quantification $\exists p. \varphi$ in WMSO requires p to be interpreted over a finite subset of an LTS. We identify a notion of *continuity* as the modal counterpart of this constraint, and call the resulting logic $\mu_C\text{ML}$, the *continuous* μ -calculus. This fragment of μML , which was introduced in [van Benthem 2006] under the name of “ ω - μ -calculus”, can be defined by the same grammar as the full μML ,

$$\varphi ::= q \mid \neg\varphi \mid \varphi \vee \varphi \mid \Diamond\varphi \mid \mu p. \varphi'$$

with the difference that φ' does not just need to be positive in p , but also continuous in p . This terminology refers to the fact that φ' is interpreted by a function that is continuous with respect to the Scott topology; as we shall see in Section 3, p -continuity can be given a *syntactic* characterisation, as a certain fragment of μML which will be used to define the logic $\mu_C\text{ML}$.

For our second result (6), we move in the opposite direction. That is, we look for a natural second-order logic of which $\mu_N\text{ML}$ is the bisimulation-invariant fragment. Symmetrically to the case (5) of WMSO and continuity, a crucial aspect is to identify which constraint on second-order quantification corresponds to the constraint on fixpoint alternation expressed by $\mu_N\text{ML}$. Our analysis stems from the observation that, when a formula $\mu p. \varphi$ of $\mu_N\text{ML}$ is satisfied in a tree model \mathbb{T} , the interpretation of p must be a subset of a *conversely well-founded* subtree of \mathbb{T} , because alternation-freedom prevents p from occurring in a ν -subformula of φ . We introduce the concept of a *noetherian* subset as a generalisation of this property from trees to arbitrary LTSs: intuitively, a subset of a LTS \mathbb{S} is called noetherian if it is a subset of a bundle of paths that does not contain any infinite ascending chain. (Precise definitions will be supplied in Section 3.) The logic NMSO appearing in (6), which we call *noetherian* second-order logic, is the variation of MSO restricting second-order quantification to noetherian subsets.

A unifying perspective over these results can be given through the lens of König's lemma, saying that a subset of a tree \mathbb{T} is finite precisely when it is included in a subtree of \mathbb{T} which is both finitely branching and conversely well-founded. In other words, finiteness on trees has two components, a *horizontal* (finite branching) and a *vertical* (well-foundedness) dimension. The bound imposed by NMSO-quantification acts only on the *vertical* dimension, whereas WMSO-quantification acts on both. It then comes at no surprise that (5)-(6) collapse to (4) on finitely branching trees. The restriction to (unbounded) finitely branching models nullifies the difference between noetherian and finite, equating WMSO and NMSO (and thus also $\mu_N\text{ML}$ and $\mu_C\text{ML}$).

Another interesting observation concerns the relative expressive power of WMSO with respect to standard MSO. As mentioned above, WMSO is *not* strictly weaker than SMSO on arbitrary LTSs. Nonetheless, putting together (3) and (5) reveals that WMSO collapses within the boundaries of SMSO-expressiveness when it comes to bisimulation-invariant formulas, because $\mu_C\text{ML}$ is strictly weaker than μML . In fact, modulo bisimilarity, WMSO turns out to be even weaker than NMSO, as $\mu_C\text{ML}$ is also a fragment of $\mu_N\text{ML}$. In a sense, this new landscape of results tells us that the feature distinguishing WMSO from SMSO/NMSO, *viz.* the ability of expressing cardinality properties of the horizontal dimension of models, disappears once we focus on the bisimulation-invariant part, and thus is not computationally relevant.

1.2. Automata-theoretic characterisations

Janin & Walukiewicz's proof of (3) passes through a characterisation of the two logics involved in terms of *parity automata*. In a nutshell, a parity automaton $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ processes LTSs as inputs, according to a transition function Δ defined in terms of a so-called *one-step logic* $L_1(A)$, where the states A of \mathbb{A} may occur as unary predicates. The map $\Omega: A \rightarrow \mathbb{N}$ assigns to each state a *priority*; if the least priority value occurring infinitely often during the computation is even, the input is accepted. Both SMSO and μML are characterised by classes of parity automata: what changes is just the one-step logic, which is, respectively, first-order logic with (FOE_1) and without (FO_1) equality.

$$\text{SMSO} \equiv \text{Aut}(\text{FOE}_1) \quad (\text{over the class of all trees}), \quad (7)$$

$$\mu\text{ML} \equiv \text{Aut}(\text{FO}_1) \quad (\text{over the class of all LTSs}). \quad (8)$$

This kind of automata-theoretic characterisation, which we believe is of independent interest, also underpins our two correspondence results. As the second main contribution of this paper, we introduce new classes of parity automata that exactly capture the expressive power of the second-order languages WMSO and NMSO (over tree models), and of the modal languages $\mu_C\text{ML}$ and $\mu_N\text{ML}$ (over arbitrary models).

Let us start from the simpler case, that is NMSO and $\mu_N\text{ML}$. As mentioned above, the leading intuition for these logics is that they are constrained in what can be expressed about the *vertical* dimension of models. In automata-theoretic terms, we translate this constraint into the requirement that runs of an automaton can see at most one parity infinitely often: this yields the class of so-called *weak* parity automata [Muller et al. 1992], which we write $\text{Aut}_w(L_1)$ for a given one-step logic L_1 .¹ We shall show:

¹Interestingly, [Muller et al. 1992] introduces the class $\text{Aut}_w(\text{FOE}_1)$ in order to show that it characterises WMSO on finitely branching trees, whence the name of *weak* automata. As discussed above, this correspondence is an “optical illusion”, due to the restricted class of models that are considered, on which $\text{NMSO} = \text{WMSO}$.

THEOREM 1.2.

$$\text{NMSO} \equiv \text{Aut}_w(\text{FOE}_1) \quad (\text{over the class of all trees}), \quad (9)$$

$$\mu_N\text{ML} \equiv \text{Aut}_w(\text{FO}_1) \quad (\text{over the class of all LTSs}). \quad (10)$$

It is worth to zoom in on our main point of departure from Janin & Walukiewicz' proofs of (7)-(8). In the characterisation (7), due to [Walukiewicz 1996], a key step is to show that each automaton in $\text{Aut}(\text{FOE}_1)$ can be simulated by an equivalent *non-deterministic* automaton of the same class. This is instrumental in the projection construction, allowing to build an automaton equivalent to $\exists p.\varphi \in \text{MSO}$ starting from an automaton for φ . Our counterpart (9) is also based on a simulation theorem. However, we cannot proceed in the same manner, as the class $\text{Aut}_w(\text{FOE}_1)$, unlike $\text{Aut}(\text{FOE}_1)$, is *not* closed under non-deterministic simulation. Thus we devise a different construction, which starting from a weak automaton \mathbb{A} creates an equivalent automaton \mathbb{A}' which acts non-deterministically only on a *conversely well-founded* part of each accepted tree. It turns out that the class $\text{Aut}_w(\text{FOE}_1)$ is closed under this variation of the simulation theorem; moreover, the property of \mathbb{A}' is precisely what is needed to make a projection construction that mirrors NMSO-quantification.

We now consider the automata-theoretic characterisation of WMSO and $\mu_C\text{ML}$. Whereas in (9)-(10) the focus was on the vertical dimension of a given model, the constraint that we now need to translate into automata-theoretic terms concerns both *vertical* and *horizontal* dimension. Our revision of (7)-(8) thus moves on two different axes. The constraint on the vertical dimension is handled analogously to the cases (9)-(10), by switching from standard to *weak* parity automata. The constraint on the horizontal dimension requires more work. The first problem lies in finding the right one-step logic, which should be able to express cardinality properties, as WMSO is able to do. An obvious candidate would be weak monadic second-order logic itself, or more precisely, its variation WMSO_1 over the signature of unary predicates (corresponding to the automata states). A very helpful observation from [Väänänen 1977] is that we can actually work with an equivalent formalism which is better tailored to our aims. Indeed, $\text{WMSO}_1 \equiv \text{FOE}_1^\infty$, where FOE_1^∞ is the extension of FOE_1 with the generalised quantifier \exists^∞ , with $\exists^\infty x.\varphi$ stating the existence of *infinitely* many objects satisfying φ .

At this stage, our candidate automata class for WMSO could be $\text{Aut}_w(\text{FOE}_1^\infty)$. However, this fails because FOE_1^∞ bears too much expressive power: since it extends FOE_1 , we would find that, over tree models, $\text{Aut}_w(\text{FOE}_1^\infty)$ extends $\text{Aut}_w(\text{FOE}_1)$, whereas we already saw that $\text{Aut}_w(\text{FOE}_1) \equiv \text{NMSO}$ is incomparable to WMSO. It is here that we crucially involve the notion of *continuity*. For a class $\text{Aut}_w(L_1)$ of weak parity automata, we call *continuous-weak* parity automata, forming a class $\text{Aut}_{wc}(L_1)$, those satisfying the following additional constraint:

- for every state a with even priority $\Omega(a)$, every one-step formula $\varphi \in L_1(A)$ defining the transitions from a has to be continuous in all states a' lying in a cycle with a ; dually, if $\Omega(a)$ is odd, every such φ has to be a' -cocontinuous.²

We can now formulate our characterisation result as follows.

THEOREM 1.3.

$$\text{WMSO} \equiv \text{Aut}_{wc}(\text{FOE}_1^\infty) \quad (\text{over the class of trees}), \quad (11)$$

$$\mu_C\text{ML} \equiv \text{Aut}_{wc}(\text{FO}_1) \quad (\text{over the class of all LTSs}). \quad (12)$$

²It is important to stress that, even though continuity is a semantic condition, we have a *syntactic* characterisation of FOE_1^∞ -formulas satisfying it (see [Carreiro et al. 2018]), meaning that $\text{Aut}_{wc}(\text{FOE}_1^\infty)$ is definable independently of the structures taken as input.

Thus automata for WMSO deviate from SMSO-automata $Aut(FOE_1)$ on two different levels: at the global level of the automaton run, because of the weakness and continuity constraint, and at the level of the one-step logic defining a single transition step. Another interesting point stems from pairing (11)-(12) with the expressive completeness result (5): although automata for WMSO are based on a more powerful one-step logic (FOE_1^∞) than those for $\mu_C ML$ (FO_1), modulo bisimilarity they characterise the same expressiveness. This connects back to our previous observation, that the ability of WMSO to express cardinality properties on the horizontal dimension vanishes in a bisimulation-invariant context.

1.3. Outline

It is useful to conclude this introduction with a roadmap of how the various results are achieved. In a nutshell, the two expressive completeness theorems (5) and (6) will be based respectively on the following two chains of equivalences:

$$\mu_N ML \equiv \mu_N FO_1 \equiv Aut_w(FO_1) \equiv Aut_w(FOE_1)/\leftrightarrow \equiv NMSO/\leftrightarrow \text{ (over LTSs)}. \quad (13)$$

$$\mu_C ML \equiv \mu_C FO_1 \equiv Aut_{wc}(FO_1) \equiv Aut_{wc}(FOE_1^\infty)/\leftrightarrow \equiv WMSO/\leftrightarrow \text{ (over LTSs)}. \quad (14)$$

After giving a precise definition of the necessary preliminaries in the Sections 2 and 3, we proceed as follows. First, Section 4 introduces parity automata parametrised over a one-step language L_1 , both in the standard ($Aut(L_1)$), weak ($Aut_w(L_1)$) and continuous-weak ($Aut_{wc}(L_1)$) form. With Theorems 4.33 and 4.34, we show that

$$\mu_N L_1 \equiv Aut_w(L_1) \quad \mu_C L_1 \equiv Aut_{wc}(L_1) \quad \text{(over LTSs)} \quad (15)$$

where $\mu_N L_1$ and $\mu_C L_1$ are extensions of L_1 with fixpoint operators subject to a “noetherianess” and a “continuity” constraint respectively. Instantiating (15) yield the second equivalence both in (13) and (14):

$$\mu_N FO_1 \equiv Aut_w(FO_1) \quad \mu_C FO_1 \equiv Aut_{wc}(FO_1) \quad \text{(over LTSs)}.$$

Next, in Section 5, Theorem 5.2, we show how to construct from a WMSO-formula an equivalent automaton of the class $Aut_{wc}(FOE_1^\infty)$. In Section 6, Theorem 6.2, we show the analogous characterisation for NMSO and $Aut_w(FOE_1)$. These two sections yield part of the last equivalence in (14) and in (13) respectively.

$$Aut_w(FOE_1) \geq NMSO \quad Aut_{wc}(FOE_1^\infty) \geq WMSO \quad \text{(over trees)}. \quad (16)$$

Notice that, differently from all the other proof pieces, (16) only holds on trees, because the projection construction for automata relies on the input LTSs being tree shaped.

Section 7 yields the remaining bit of the automata characterisations. Theorem 7.1 shows

$$\mu_N FOE_1 \leq NMSO \quad \mu_C FOE_1^\infty \leq WMSO \quad \text{(over LTSs)},$$

which, paired with (15), yields

$$Aut_w(FOE_1) \equiv \mu_N FOE_1 \leq NMSO \quad Aut_{wc}(FOE_1^\infty) \equiv \mu_C FOE_1^\infty \leq WMSO \text{ (over LTSs)}.$$

Putting the last equation and (16) together we have our automata characterisations

$$Aut_w(FOE_1) \equiv NMSO \quad Aut_{wc}(FOE_1^\infty) \equiv WMSO \quad \text{(over trees)}.$$

which also yields the rightmost equivalence in (14) and in (13), because any LTS is bisimilar to its tree unraveling.

$$Aut_w(FOE_1)/\leftrightarrow \equiv NMSO/\leftrightarrow \quad Aut_{wc}(FOE_1^\infty)/\leftrightarrow \equiv WMSO/\leftrightarrow \quad \text{(over LTSs)}.$$

At last, Section 8 is split into two parts. First, Theorem 8.1 extends the results in Section 4 to complete the following chains of equivalences, yielding the first block in

(13) and in (14).

$$\mu_N \text{ML} \equiv \mu_N \text{FO}_1 \equiv \text{Aut}_w(\text{FO}_1) \qquad \mu_C \text{ML} \equiv \mu_C \text{FO}_1 \equiv \text{Aut}_{wc}(\text{FO}_1) \qquad (\text{over LTSs}).$$

As a final step, Subsection 8.2 fills the last gap in (13)-(14) by showing

$$\text{Aut}_w(\text{FO}_1) \equiv \text{Aut}_w(\text{FOE}_1) / \Leftrightarrow \qquad \text{Aut}_{wc}(\text{FO}_1) \equiv \text{Aut}_{wc}(\text{FOE}_1^\infty) / \Leftrightarrow \qquad (\text{over LTSs}).$$

1.4. Conference versions and companion paper

This journal article is based on two conference papers [Facchini et al. 2013; Carreiro et al. 2014], which were based in their turn on a Master thesis [Zanasi 2012] and a PhD dissertation [Carreiro 2015]. Each of the two conference papers focussed on a single expressive completeness theorem between (5) and (6): presenting both results in a mostly uniform way has required an extensive overhaul, involving the development of new pieces of theory, as in particular in the Sections 4, 7 and 8. All missing proofs of the conference papers are included and the simulation theorem for NMSO- and WMSO-automata is simplified, as it is now based on macro-states that are sets instead of relations. Moreover, we amended two technical issues with the characterisation $\mu_N \text{ML} \equiv \text{NMSO} / \Leftrightarrow$ presented in [Facchini et al. 2013]. First, the definition of noetherian subset in NMSO has been made more precise, in order to prevent potential misunderstandings arising with the formulation in [Facchini et al. 2013]. Second, as stated in [Facchini et al. 2013] the expressive completeness result was only valid on trees. In this version, we extend it to arbitrary LTSs, thanks to the new material in Section 7.

Finally, our approach depends on model-theoretic results on the three main one-step logics featuring in this paper: FO_1 , FOE_1 and FOE_1^∞ . We believe these results to be of independent interest, and in order to save some space here, we decided to restrict our discussion of the model theory of these monadic predicate logics in this paper to a summary. Full details can be found in the companion paper [Carreiro et al. 2018].

2. PRELIMINARIES

We assume the reader to be familiar with the syntax and (game-theoretic) semantics of the modal μ -calculus and with the automata-theoretic perspective on this logic. For background reading we refer to [Grädel et al. 2002; Venema 2012]; the purpose of this section is to fix some notation and terminology.

2.1. Transition systems and trees

Throughout this article we fix a set Prop of elements that will be called *proposition letters* and denoted with small Latin letters p, q, \dots . We will often focus on a finite subset $P \subseteq_{\omega} \text{Prop}$, and denote with C the set $\wp(P)$ of *labels* on P ; it will be convenient to think of C as an *alphabet*. Given a binary relation $R \subseteq X \times Y$, for any element $x \in X$, we indicate with $R[x]$ the set $\{y \in Y \mid (x, y) \in R\}$ while R^+ and R^* are defined respectively as the transitive closure of R and the reflexive and transitive closure of R . The set $\text{Ran}(R)$ is defined as $\bigcup_{x \in X} R[x]$.

A *P-labeled transition system* (LTS) is a tuple $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ where T is the universe or domain of \mathbb{S} , $\kappa : T \rightarrow \wp(P)$ is a colouring (or marking), $R \subseteq T^2$ is the accessibility relation and $s_I \in T$ is a distinguished node. We call $\kappa(s)$ the colour, or type, of node $s \in T$. Observe that the colouring $\kappa : T \rightarrow \wp(P)$ can be seen as a valuation $\kappa^{\sharp} : P \rightarrow \wp(T)$ given by $\kappa^{\sharp}(p) := \{s \in T \mid p \in \kappa(s)\}$. A *P-tree* is a P-labeled LTS in which every node can be reached from s_I , and every node except s_I has a unique predecessor; the distinguished node s_I is called the *root* of \mathbb{S} . Each node $s \in T$ uniquely defines a subtree of \mathbb{S} with carrier $R^*[s]$ and root s . We denote this subtree by $\mathbb{S}.s$.

A *path* through an LTS $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ is a sequence $(s_i)_{i < \alpha}$, where α is finite but non-zero, or $\alpha = \omega$, and $(s_i, s_{i+1}) \in R$ whenever $i + 1 < \alpha$. In particular we allow paths of the form s , for any $s \in S$. A tree is called *conversely well-founded* if it does not contain any infinite path.

The *tree unravelling* of an LTS \mathbb{S} is given by $\hat{\mathbb{S}} := \langle T_P, R_P, \kappa', s_I \rangle$ where T_P is the set of finite paths in \mathbb{S} stemming from s_I , $R_P(t, t')$ iff t' is a one-step extension of t and the colour of a path $t \in T_P$ is given by the colour of its last node in T . The ω -*unravelling* \mathbb{S}^ω of \mathbb{S} is defined similarly, now taking as nodes all “generalised” paths of the form $(s_I, n_1, s_1, \dots, n_k, s_k)$ where $n_i \in \omega$ for each i .

A *p-variant* of a transition system $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ is a $P \cup \{p\}$ -transition system $\langle T, R, \kappa', s_I \rangle$ such that $\kappa'(s) \setminus \{p\} = \kappa(s) \setminus \{p\}$ for all $s \in T$. Given a set $S \subseteq T$, we let $\mathbb{S}[p \mapsto S]$ denote the *p-variant* where $p \in \kappa'(s)$ iff $s \in S$.

Let $\varphi \in L$ be a formula of some logic L , we use $\text{Mod}_L(\varphi) = \{\mathbb{S} \mid \mathbb{S} \models \varphi\}$ to denote the class of transition systems that make φ true. The subscript L will be omitted when L is clear from context. A class C of transition systems is said to be *L-definable* if there is a formula $\varphi \in L$ such that $\text{Mod}_L(\varphi) = C$. We use the notation $\varphi \equiv \psi$ to mean that $\text{Mod}_L(\varphi) = \text{Mod}_L(\psi)$ and given two logics L, L' we use $L \equiv L'$ when the L -definable and L' -definable classes of models coincide.

2.2. Games

We introduce some terminology and background on infinite games. All the games that we consider involve two players called *Éloise* (\exists) and *Abelard* (\forall). In some contexts we refer to a player Π to specify a generic player in $\{\exists, \forall\}$. Given a set A , by A^* and A^ω we denote respectively the set of words (finite sequences) and streams (or infinite words) over A .

A *board game* \mathcal{G} is a tuple $(G_\exists, G_\forall, E, \text{Win})$, where G_\exists and G_\forall are disjoint sets whose union $G = G_\exists \cup G_\forall$ is called the *board* of \mathcal{G} , $E \subseteq G \times G$ is a binary relation encoding the *admissible moves*, and $\text{Win} \subseteq G^\omega$ is a *winning condition*. An *initialized board game* $\mathcal{G}@u_I$ is a tuple $(G_\exists, G_\forall, u_I, E, \text{Win})$ where $u_I \in G$ is the *initial position* of the game.

In a *parity game*, the set Win is given by a *parity function*, that is, a map $\Omega : G \rightarrow \omega$ of finite range, in the sense that a sequence $(a_i)_{i < \omega}$ belongs to Win iff the maximal value n that is reached as $n = \Omega(a_i)$ for infinitely many i , is even.

Given a board game \mathcal{G} , a *match* of \mathcal{G} is simply a path through the graph (G, E) ; that is, a sequence $\pi = (u_i)_{i < \alpha}$ of elements of G , where α is either ω or a natural number, and $(u_i, u_{i+1}) \in E$ for all i with $i + 1 < \alpha$. A match of $\mathcal{G}@u_I$ is supposed to start at u_I . Given a finite match $\pi = (u_i)_{i < k}$ for some $k < \omega$, we call $\text{last}(\pi) := u_{k-1}$ the *last position* of the match; the player Π such that $\text{last}(\pi) \in G_\Pi$ is supposed to move at this position, and if $E[\text{last}(\pi)] = \emptyset$, we say that Π *got stuck* in π . A match π is called *total* if it is either finite, with one of the two players getting stuck, or infinite. Matches that are not total are called *partial*. Any total match π is *won* by one of the players: If π is finite, then it is won by the opponent of the player who gets stuck. Otherwise, if π is infinite, the winner is \exists if $\pi \in \text{Win}$, and \forall if $\pi \notin \text{Win}$.

Given a board game \mathcal{G} and a player Π , let PM_Π^G denote the set of partial matches of \mathcal{G} whose last position belongs to player Π . A *strategy* for Π is a function $f : \text{PM}_\Pi^G \rightarrow G$. A match $\pi = (u_i)_{i < \alpha}$ of \mathcal{G} is *f-guided* if for each $i < \alpha$ such that $u_i \in G_\Pi$ we have that $u_{i+1} = f(u_0, \dots, u_i)$. Let $u \in G$ and a f be a strategy for Π . We say that f is a *surviving strategy* for Π in $\mathcal{G}@u$ if for each f -guided partial match π of $\mathcal{G}@u$, if $\text{last}(\pi)$ is in G_Π then $f(\pi)$ is legitimate, that is, $(\text{last}(\pi), f(\pi)) \in E$. We say that f is a *winning strategy* for Π in $\mathcal{G}@u$ if, additionally, Π wins each f -guided total match of $\mathcal{G}@u$. If Π has a winning strategy for $\mathcal{G}@u$ then u is called a *winning position* for Π in \mathcal{G} . The set of positions of \mathcal{G} that are winning for Π is denoted by $\text{Win}_\Pi(\mathcal{G})$.

A strategy f is called *positional* if $f(\pi) = f(\pi')$ for each $\pi, \pi' \in \text{Dom}(f)$ with $\text{last}(\pi) = \text{last}(\pi')$. A board game \mathcal{G} with board G is *determined* if $G = \text{Win}_\exists(\mathcal{G}) \cup \text{Win}_\forall(\mathcal{G})$, that is, each $u \in G$ is a winning position for one of the two players. The next result states that parity games are positionally determined.

FACT 2.1 ([EMERSON AND JUTLA 1991; MOSTOWSKI 1991]). *For each parity game \mathcal{G} , there are positional strategies f_\exists and f_\forall respectively for player \exists and \forall , such that for every position $u \in G$ there is a player Π such that f_Π is a winning strategy for Π in $\mathcal{G}@u$.*

In the sequel we will often assume, without notification, that strategies in parity games are positional. Moreover, we think of a positional strategy f_Π for player Π as a function $f_\Pi : G_\Pi \rightarrow G$.

2.3. The Modal μ -Calculus

The language of the modal μ -calculus (μML) is given by the following grammar:

$$\varphi ::= q \mid \neg q \mid \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \Diamond \varphi \mid \Box \varphi \mid \mu p. \varphi \mid \nu p. \varphi$$

where $p, q \in \text{Prop}$ and p is positive in φ (i.e., p is not negated). We will freely use standard syntactic concepts and notations related to this language, such as the sets $FV(\varphi)$ and $BV(\varphi)$ of *free* and *bound* variables of φ , and the collection $Sfor(\varphi)$ of subformulas of φ . We use the standard convention that no variable is both free and bound in a formula and that every bound variable is fresh. We let $\mu\text{ML}(P)$ denote the collection of formulas φ with $FV(\varphi) \subseteq P$. Sometimes we write $\psi \leq \varphi$ to denote that ψ is a subformula of φ . For a bound variable p occurring in some formula $\varphi \in \mu\text{ML}$, we use δ_p to denote the binding definition of p , that is, the unique formula such that either $\mu p. \delta_p$ or $\nu p. \delta_p$ is a subformula of φ .

We need some notation for the notion of *substitution*. Let φ and $\{\psi_z \mid z \in Z\}$ be modal fixpoint formulas, where $Z \cap BV(\varphi) = \emptyset$. Then we let $\varphi[\psi_z/z \mid z \in Z]$ denote the formula obtained from φ by simultaneously substituting each formula ψ_z for z in

φ (with the usual understanding that no free variable in any of the ψ_z will get bound by doing so). In case Z is a singleton z , we will simply write $\varphi[\psi_z/z]$, or $\varphi[\psi]$ if z is clear from context.

The semantics of this language is completely standard. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ be a transition system and $\varphi \in \mu\text{ML}$. We inductively define the *meaning* $\llbracket \varphi \rrbracket^{\mathbb{S}}$ which includes the following clauses for the least (μ) and greatest (ν) fixpoint operators:

$$\begin{aligned} \llbracket \mu p. \psi \rrbracket^{\mathbb{S}} &:= \bigcap \{ X \subseteq T \mid X \supseteq \psi_p^{\mathbb{S}}(X) \} \\ \llbracket \nu p. \psi \rrbracket^{\mathbb{S}} &:= \bigcup \{ X \subseteq T \mid X \subseteq \psi_p^{\mathbb{S}}(X) \}, \end{aligned}$$

where the map $\psi_p^{\mathbb{S}} : \wp(T) \rightarrow \wp(T)$ represents how the meaning of ψ depends on that of p :

$$\psi_p^{\mathbb{S}}(X) := \llbracket \psi \rrbracket^{\mathbb{S}[p \mapsto X]}$$

We say that φ is *true* in \mathbb{S} (notation $\mathbb{S} \models \varphi$) iff $s_I \in \llbracket \varphi \rrbracket^{\mathbb{S}}$.

We will now describe the semantics defined above in game-theoretic terms. That is, we will define the evaluation game $\mathcal{E}(\varphi, \mathbb{S})$ associated with a formula $\varphi \in \mu\text{ML}$ and a transition system \mathbb{S} . This game is played by two players (\exists and \forall) moving through positions (ξ, s) where $\xi \trianglelefteq \varphi$ and $s \in T$. In an arbitrary position (ξ, s) it is useful to think of \exists trying to show that ξ is true at s , and of \forall of trying to convince her that ξ is false at s . The rules of the evaluation game are given in the following table.

Position	Player	Admissible moves
$(\psi_1 \vee \psi_2, s)$	\exists	$\{(\psi_1, s), (\psi_2, s)\}$
$(\psi_1 \wedge \psi_2, s)$	\forall	$\{(\psi_1, s), (\psi_2, s)\}$
$(\Diamond \varphi, s)$	\exists	$\{(\varphi, t) \mid t \in R[s]\}$
$(\Box \varphi, s)$	\forall	$\{(\varphi, t) \mid t \in R[s]\}$
$(\mu p. \varphi, s)$	$-$	$\{(\varphi, s)\}$
$(\nu p. \varphi, s)$	$-$	$\{(\varphi, s)\}$
(p, s) with $p \in BV(\varphi)$	$-$	$\{(\delta_p, s)\}$
$(\neg q, s)$ with $q \in FV(\varphi)$ and $q \notin \kappa(s)$	\forall	\emptyset
$(\neg q, s)$ with $q \in FV(\varphi)$ and $q \in \kappa(s)$	\exists	\emptyset
(q, s) with $q \in FV(\varphi)$ and $q \in \kappa(s)$	\forall	\emptyset
(q, s) with $q \in FV(\varphi)$ and $q \notin \kappa(s)$	\exists	\emptyset

Every finite match of this game is lost by the player that got stuck. To give a winning condition for an infinite match let p be, of the bound variables of φ that get unravelled infinitely often, the one such that δ_p the highest subformula in the syntactic tree of φ . The winner of the match is \forall if p is a μ -variable and \exists if p is a ν -variable. We say that φ is true in \mathbb{S} iff \exists has a winning strategy in $\mathcal{E}(\varphi, \mathbb{S})$.

PROPOSITION 2.2 (ADEQUACY THEOREM). *Let $\varphi = \varphi(p)$ be a formula of μML in which all occurrences of p are positive, \mathbb{S} be a LTS and $s \in T$. Then:*

$$s \in \llbracket \mu p. \varphi \rrbracket^{\mathbb{S}} \iff (\mu p. \varphi, s) \in \text{Win}_{\exists}(\mathcal{E}(\mu p. \varphi, \mathbb{S})). \quad (17)$$

2.4. Bisimulation

Bisimulation is a notion of behavioral equivalence between processes. For the case of transition systems, it is formally defined as follows.

Definition 2.3. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ and $\mathbb{S}' = \langle T', R', \kappa', s'_I \rangle$ be P-labeled transition systems. A *bisimulation* is a relation $Z \subseteq T \times T'$ such that for all $(t, t') \in Z$ the following holds:

(*atom*). $\kappa(t) = \kappa'(t')$;
 (*forth*). for all $s \in R[t]$ there is $s' \in R'[t']$ such that $(s, s') \in Z$;
 (*back*). for all $s' \in R'[t']$ there is $s \in R[t]$ such that $(s, s') \in Z$.

Two pointed transition systems \mathbb{S} and \mathbb{S}' are *bisimilar* (denoted $\mathbb{S} \Leftrightarrow \mathbb{S}'$) if there is a bisimulation $Z \subseteq T \times T'$ containing (s_I, s'_I) .

The following observation about tree unravellings is the key to understand the importance of tree models in the setting of invariance modulo bisimilarity results.

FACT 2.4. $\mathbb{S}, \hat{\mathbb{S}}$ and \mathbb{S}^ω are bisimilar, for every transition system \mathbb{S} .

A class C of transition systems is *bisimulation closed* if $\mathbb{S} \Leftrightarrow \mathbb{S}'$ implies that $\mathbb{S} \in C$ iff $\mathbb{S}' \in C$, for all \mathbb{S} and \mathbb{S}' . A formula $\varphi \in L$ is *bisimulation-invariant* if $\mathbb{S} \Leftrightarrow \mathbb{S}'$ implies that $\mathbb{S} \models \varphi$ iff $\mathbb{S}' \models \varphi$, for all \mathbb{S} and \mathbb{S}' .

FACT 2.5. Each μML -definable class of transition systems is bisimulation closed.

3. MONADIC SECOND-ORDER LOGICS AND MODAL μ -CALCULI

In this section we introduce the main logics of our narrative, i.e., the weak and noetherian versions of monadic second-order logic on the one hand, and the continuous and noetherian fragments of the modal μ -calculus on the other. We also briefly discuss some model-theoretic properties and results related to these logics.

3.1. Monadic second-order logics

Three variations of monadic second-order logic feature in our work: *standard*, *weak*, and *noetherian* monadic second-order logic, and for each of these three variations, we consider a one-sorted and a two-sorted version. As we will see later, the one-sorted version fits better in the automata-theoretic framework, whereas it is more convenient to use the two-sorted approach when translating μ -calculi to second order languages. In both the one-sorted and the two-sorted version, the syntax of the three languages is the same, the difference lying in the semantics, more specifically, in the type of subsets over which the second-order quantifiers range. In the case of standard and weak monadic second-order logic, these quantifiers range over all, respectively, all finite subsets of the model. In the case of NMSO we need the concept of a *noetherian* subset of an LTS.

Definition 3.1. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ be an LTS, and let B be a set of finite paths that all share the same starting point s ; we call B a *bundle rooted at s* , or simply an *s -bundle*, if B does not contain an infinite ascending chain $\pi_0 \sqsubset \pi_1 \sqsubset \dots$, where \sqsubset denotes the (strict) initial-segment relation on paths. A *bundle* is simply an s -bundle for some $s \in T$. Finally, a subset X of T is called *noetherian* if there is a bundle B such that each $t \in X$ lies on some path in B .

Example 3.2. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ be a labelled transition system.

- (1) Since the empty bundle is a bundle, the empty set is a noetherian set in \mathbb{S} .
- (2) In case \mathbb{S} is a conversely well-founded tree, the set of all paths emanating from s_I is a bundle, and therefore *every* subset of T is noetherian.
- (3) More generally, if \mathbb{S} is an arbitrary tree, its noetherian subsets coincide with those that are included in a well-founded subtree of \mathbb{S} . In case \mathbb{S} is finitely branching, every well-founded subtree is finite; as a consequence, every noetherian subset is finite.
- (4) Let s be some arbitrary node in \mathbb{S} , and suppose that the points s_1, \dots, s_n are all reachable from s (i.e., belong to the set $R^*[s]$). Then for each i we may fix a (finite) path π_i from s to s_i . Clearly these paths, taken together, provide a bundle, and so the set $\{s_1, \dots, s_n\}$ is noetherian.
- (5) This means in particular that every singleton is noetherian. Furthermore, if \mathbb{S} is finite, and every point in \mathbb{S} is reachable from s_I , then every subset of T is noetherian.
- (6) Similarly, every finite subset of a tree is noetherian. Hence, on finitely branching trees, the noetherian sets coincide with the finite ones.

One-sorted monadic second-order logics

Definition 3.3. The formulas of the *(one-sorted) monadic second-order language* are defined by the following grammar:

$$\varphi ::= \Downarrow p \mid p \sqsubseteq q \mid R(p, q) \mid \neg \varphi \mid \varphi \vee \varphi \mid \exists p. \varphi,$$

where p and q are letters from Prop. We adopt the standard convention that no proposition letter is both free and bound in φ .

As mentioned, the three logics SMSO, WMSO and NMSO are distinguished by their semantics. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ be an LTS. The interpretation of the atomic formulas is

fixed:

$$\begin{aligned} \mathbb{S} \models \Downarrow p & \text{ iff } \kappa^{\mathbb{h}}(p) = \{s_I\} \\ \mathbb{S} \models p \sqsubseteq q & \text{ iff } \kappa^{\mathbb{h}}(p) \subseteq \kappa^{\mathbb{h}}(q) \\ \mathbb{S} \models R(p, q) & \text{ iff for every } s \in \kappa^{\mathbb{h}}(p) \text{ there exists } t \in \kappa^{\mathbb{h}}(q) \text{ such that } sRt. \end{aligned}$$

Furthermore, the interpretation of the boolean connectives is standard. The interpretation of the existential quantifier is where the logics diverge:

$$\mathbb{S} \models \exists p. \varphi \text{ iff } \mathbb{S}[p \mapsto X] \models \varphi \left\{ \begin{array}{ll} \text{for some} & (\text{SMSO}) \\ \text{for some finite} & (\text{WMSO}) \\ \text{for some noetherian} & (\text{NMSO}) \end{array} \right\} X \subseteq T.$$

Observe that for a given monadic second-order formula φ , the classes $\text{Mod}_{\text{SMSO}}(\varphi)$, $\text{Mod}_{\text{WMSO}}(\varphi)$ and $\text{Mod}_{\text{NMSO}}(\varphi)$ will generally be different.

Two-sorted monadic second-order logics. The reader may have expected to see the following more standard language for second-order logic.

Definition 3.4. Given a set iVar of individual (first-order) variables, we define the formulas of the *two-sorted monadic second-order language* by the following grammar:

$$\varphi ::= p(x) \mid R(x, y) \mid x \approx y \mid \neg \varphi \mid \varphi \vee \varphi \mid \exists x. \varphi \mid \exists p. \varphi$$

where $p \in \text{Prop}$, $x, y \in \text{iVar}$ and \approx is the symbol for equality.

Formulas are interpreted over an LTS $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ with a variable assignment $g : \text{iVar} \rightarrow T$, and the semantics of the language is completely standard. Depending on whether second-order quantification ranges over all subsets, over finite subsets or over noetherian subsets, we obtain the three two-sorted variations denoted respectively as 2SMSO, 2WMSO and 2NMSO.

Equivalence of one-sorted and two-sorted MSO. In each variation, the one-sorted and the two-sorted versions can be proved to be equivalent, but there is a subtlety due to the fact that our models have a distinguished state. In the one-sorted language, we use the downarrow \Downarrow to access this distinguished state; in the two-sorted approach, we will use a *fixed* variable v to refer to the distinguished state, and given a formula $\varphi(v)$ of which v is the only free individual variable, we write $\mathbb{S} \models \varphi[s_I]$ rather than $\mathbb{S}[v \mapsto s_I] \models \varphi$. As a consequence, the proper counterpart of the one-sorted language SMSO is the set $2\text{SMSO}(v)$ of those 2SMSO-formulas that have precisely v as their unique free variable.

More in particular, with $L \in \{\text{SMSO}, \text{WMSO}, \text{NMSO}\}$, we say that $\varphi \in L$ is *equivalent* to $\psi(v) \in L(v)$ if

$$\mathbb{S} \models \varphi \text{ iff } \mathbb{S} \models \psi[s_I]$$

for every model $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$. We can now state the equivalence between the two approaches to monadic second-order logic as follows.

PROPOSITION 3.5. *Let $L \in \{\text{SMSO}, \text{WMSO}, \text{NMSO}\}$ be a monadic second-order logic.*

- (1) *There is an effective construction transforming a formula $\varphi \in L$ into an equivalent formula $\varphi^t \in 2L(v)$.*
- (2) *There is an effective construction transforming a formula $\psi \in 2L(v)$ into an equivalent formula $\psi^o \in L$.*

PROOF. Since it is completely straightforward to define a translation $(\cdot)^t$ as required for part (1) of Proposition 3.5, we only discuss the proof of part (2). The key observation here is that a single-sorted language can interpret the corresponding two-sorted language by encoding every individual variable $x \in \text{iVar}$ as a set variable p_x denoting a singleton, and that it is easy to write down a formula stating that a variable indeed is interpreted by a singleton. As a consequence, where $2L(P, X)$ denotes the set of $2L$ -formulas with free second-order variables in P and free first-order variables in X , it is not hard to formulate a translation $(\cdot)^m : 2L(P, X) \rightarrow L(P \uplus \{p_x \mid x \in X\})$ such that, for every model \mathbb{S} , every variable assignment g and every formula $\psi \in 2L(\text{Prop}, X)$:

$$\mathbb{S}, g \models \psi \quad \text{iff} \quad \mathbb{S}[p_x \mapsto \{g(x)\} \mid x \in X] \models \psi^m.$$

From this it is immediate that any $\psi \in 2L(v)$ satisfies

$$\mathbb{S} \models \psi[s_I] \quad \text{iff} \quad \mathbb{S} \models \exists p_v (\Downarrow p_v \wedge \psi^m),$$

so that we may take $\psi^o := \exists p_v (\Downarrow p_v \wedge \psi^m)$. \square

Comparing the relative expressive power of the logics SMSO, WMSO and NMSO on finitely trees, on arbitrary trees, and on arbitrary models, we can make the following observations.

Finitely branching trees. From Example 3.2(6) it follows that on this subclass of LTS, NMSO and WMSO are equivalent. They are however both strictly included in SMSO. First of all, since being a well-founded subtree is SMSO definable, NMSO (and thus WMSO) is included in SMSO. Finally, from [Rabin 1970], we know that already on binary trees the SMSO-definable property “there is a path on which p is true infinitely often” is not WMSO definable.

Arbitrary trees. For the same reason as in the case of finitely branching trees, NMSO is strictly included in SMSO. However, WMSO is now incomparable with both NMSO and SMSO. First, it is well known that WMSO can only define properties whose topological complexity is Borel (see e.g. [ten Cate and Facchini 2011]), whereas NMSO can also define non Borel properties, such as being well-founded. Second, consider the property of having a node with infinitely many successors. This property is clearly definable in WMSO, but not in SMSO. This is due to the fact that on arbitrary trees every SMSO formula is equivalent to a MSO-automata and that every non empty MSO automata recognises a finitely branching tree (see [Walukiewicz 1996]). Since all WMSO-definable languages are closed under complementation, it therefore turns out that the language of finitely branching trees is WMSO definable, but it is not SMSO definable.

Arbitrary models. Clearly, the incomparability results on tree models carry over to the more general case; that is, on arbitrary models, WMSO is incomparable with both NMSO and SMSO, and SMSO is not included in NMSO. However, at the moment of writing, we do not know whether on arbitrary models NMSO is still included in SMSO.

These findings are summarized in Figure 1 below. Note too that there are many non-trivial properties that can be expressed in all three languages; as an example we mention “eventually always p ”, see Remark 3.13.

3.2. Some model-theoretic observations

Before we turn to the precise syntactic definition of the two fragments of μML that correspond to the monadic second-order logics WMSO and NMSO, we briefly discuss the fundamental *semantic* properties underlying these definitions. Note that such a connection underlies the framework of the modal μ -calculus itself: the syntactic proviso

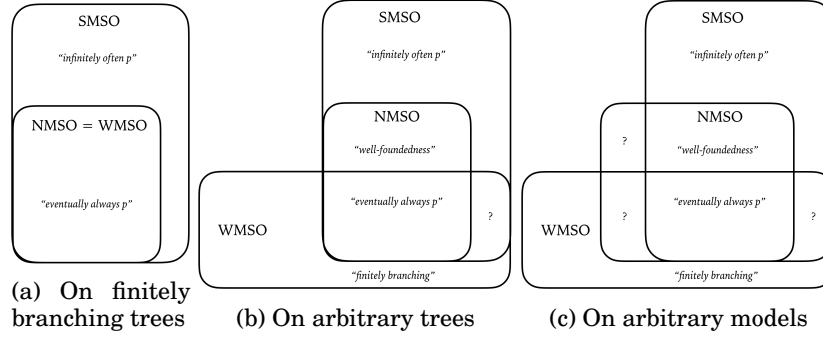

Fig. 1: Expressiveness of three monadic second order logics

on the formation of fixpoint formulas $\mu q.\varphi$ (viz., the requirement that all occurrences of q in φ are positive), guarantees a semantic property (namely: monotonicity of the associated semantic map φ_q^S), which is needed to use the Knaster-Tarski theorem to interpret the formula $\mu q.\varphi$.

The idea underlying the definition of the fragments $\mu_C\text{ML}$ and $\mu_N\text{ML}$ is to impose further conditions on the formation of fixpoint formulas $\eta q.\varphi$, to ensure that the semantic map φ_q^S satisfies some additional properties to be introduced now.

Definition 3.6. Let $F : \wp S \rightarrow \wp S$ be a map. We say that F is *monotone* if $F(X) \subseteq F(Y)$ whenever $X \subseteq Y$, and *continuous* if it is monotone and satisfies

$$F(X) = \bigcup \{F(Y) \mid Y \subseteq X, Y \text{ finite}\}. \quad (18)$$

In case S is the domain of a tree model, we call F *noetherian-based* if it is monotone and satisfies the following condition

$$F(X) = \bigcup \{F(Y) \mid Y \subseteq X, Y \text{ noetherian}\}. \quad (19)$$

In words, F is continuous if it is completely determined by its action on finite sets, and a similar perspective applies to noetherian-based maps. The name “continuity” is explained by the fact that a map $F : \wp S \rightarrow \wp S$ satisfies (18) iff F is continuous with respect to the *Scott topology* on the power set $\wp(S)$ of S . Scott continuity stems from *domain theory* [Abramsky and Jung 1994], and plays a fundamental role in many branches of logic and theoretical computer science that feature ordered structures.

What is of interest here is that we may apply the concepts of Definition 3.6 to *formulas*. To see how this works out for fixpoint formulas, recall the definition of the semantic map φ_q^S associated with a formula $\varphi \in \mu\text{ML}$ and a proposition letter q .

Definition 3.7. Let $\varphi \in \mu\text{ML}$, and q be a propositional variable. We say that φ is *monotone* (respectively, *continuous/noetherian*) in q if for every transition system S , the map $\varphi_q^S : \wp S \rightarrow \wp S$ is monotone (respectively, continuous/noetherian).

In fact, as part of the *model theory* of the modal μ -calculus, these semantic properties (and many more) can be given rather exact syntactic characterisations.

Definition 3.8. Given a set Q of propositional variables, we define the fragment $\text{Noe}_Q(\mu\text{ML})$ of μML -formulas that are (syntactically) *noetherian* in Q , by the following grammar:

$$\varphi ::= q \mid \psi \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \Diamond \varphi \mid \Box \varphi \mid \mu p.\varphi'$$

where $q \in Q$, ψ is a Q -free μML -formula, and $\varphi' \in \text{Noe}_{Q \cup \{p\}}(\mu\text{ML})$. The *co-noetherian* fragment $\text{CoNoe}_Q(\mu\text{ML})$ is defined dually by taking ν instead of μ and stating $\varphi' \in \text{CoNoe}_{Q \cup \{p\}}(\mu\text{ML})$.

Similarly, we define the fragment of μML *continuous* in Q , denoted by $\text{Con}_Q(\mu\text{ML})$, by induction in the following way

$$\varphi ::= q \mid \psi \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \Diamond \varphi \mid \mu p. \varphi'$$

where $q, p \in Q$, ψ is a Q -free μML -formula and $\varphi' \in \text{Con}_{Q \cup \{p\}}(\mu\text{ML})$. The *co-continuous* fragment $\text{CoCon}_Q(\mu\text{ML})$ is defined dually by taking ν instead of μ , \Box instead of \Diamond and stating $\varphi' \in \text{CoCon}_{Q \cup \{p\}}(\mu\text{ML})$.

FACT 3.9 ([D'AGOSTINO AND HOLLENBERG 2000; FONTAINE 2008; FONTAINE AND VENEMA 2018]).

The following hold, for any μML -formula formula φ , and any proposition letter q :

- (1) φ is monotone in q iff it is equivalent to a formula φ' which is positive in q ;
- (2) φ is continuous in q iff it is equivalent to a formula φ' in the fragment $\text{Con}_q(\mu\text{ML})$;
- (3) φ is noetherian in q iff it is equivalent to a formula φ' in the fragment $\text{Noe}_q(\mu\text{ML})$.

In passing we note that in each instance of Fact 3.9, a slightly stronger result can be proved, to the effect that it is *decidable* whether a given μ -calculus formula is monotone (resp., continuous/noetherian) in a given proposition letter.

3.3. Fragments of the modal μ -calculus

We are now ready for the definition of the fragments $\mu_N\text{ML}$ and $\mu_C\text{ML}$. Starting with the first, note that formulas of the modal μ -calculus may be classified according to their *alternation depth*, which roughly is given as the maximal length of a chain of nested alternating least and greatest fixpoint operators [Niwinski 1986]. The *alternation-free* fragment of the modal μ -calculus ($\mu_N\text{ML}$) is usually defined as the collection of μML -formulas without nesting of least and greatest fixpoint operators. It can also be given a more standard grammatical definition as the fragment of the full language where we restrict the application of the least fixpoint operator μp to formulas that are (syntactically) noetherian in p (and apply a dual condition to the greatest fixpoint operator).

Definition 3.10. The formulas of the *alternation-free* μ -calculus $\mu_N\text{ML}$ are defined by the following grammar:

$$\varphi ::= q \mid \neg q \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \Diamond \varphi \mid \Box \varphi \mid \mu p. \varphi' \mid \nu p. \varphi'',$$

where $p, q \in \text{Prop}$, $\varphi' \in \mu_N\text{ML} \cap \text{Noe}_p(\mu\text{ML})$ and dually $\varphi'' \in \mu_N\text{ML} \cap \text{CoNoe}_p(\mu\text{ML})$.

It is then immediate to verify that the above definition indeed captures exactly all formulas without alternation of least and greatest fixpoints. One may prove that a formula $\varphi \in \mu\text{ML}$ belongs to the fragment $\mu_N\text{ML}$ iff for all subformulas $\mu p. \psi_1$ and $\nu q. \psi_2$ it holds that p is not free in ψ_2 and q is not free in ψ_1 .

Similarly, we define $\mu_C\text{ML}$ to be the fragment of μML where the use of the least fixed point operator is restricted to the continuous fragment.

Definition 3.11. Formulas of the fragment $\mu_C\text{ML}$ are given by:

$$\varphi ::= q \mid \neg q \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \Diamond \varphi \mid \Box \varphi \mid \mu p. \varphi' \mid \nu p. \varphi''$$

where $p, q \in \text{Prop}$, $\varphi' \in \text{Con}_p(\mu\text{ML}) \cap \mu_C\text{ML}$, and dually $\varphi'' \in \text{CoCon}_p(\mu\text{ML}) \cap \mu_C\text{ML}$.

Characteristic about $\mu_C\text{ML}$ is that in a formula $\mu p. \varphi \in \mu_C\text{ML}$, all occurrences of p in φ are *existential* in the sense that they may be in the scope of a diamond but not of a box. Furthermore, as an immediate consequence of Fact 3.9(2) we may make the following observation.

COROLLARY 3.12. *For every $\mu_C\text{ML}$ -formula $\mu p.\varphi$, the formula φ is continuous in p .*

Finally, we consider the relative expressiveness of the fixpoint languages $\mu_C\text{ML}$, $\mu_N\text{ML}$ and μML . It is immediate from the definitions that $\mu_C\text{ML} \leq \mu_N\text{ML} \leq \mu\text{ML}$. Both inclusions are strict:

($\mu_C\text{ML} \not\leq \mu_N\text{ML}$). Consider the formula $\mu x.\Box x$ in $\mu_N\text{ML}$, stating that every path starting from the distinguished node of the model is finite. As mentioned already, on tree models this formula captures the property of being conversely well-founded, which is known not to be expressible in WMSO [ten Cate and Facchini 2011], and hence, since $\mu_C\text{ML} \leq \text{WMSO}$, not in the continuous μ -calculus either.

($\mu_N\text{ML} \not\leq \mu\text{ML}$). The property “on some path, p holds infinitely often” is definable by the μML -formula $\varphi := \nu x.\mu y.((p \vee \Diamond y) \wedge \Diamond x)$. However, this property is not definable in the alternation free fragment $\mu_N\text{ML}$. This is because, for instance, on trees, every property definable in $\mu_N\text{ML}$ is also recognised by a Büchi-automata (see e.g. [Kupferman and Vardi 2003]), whereas “infinitely often p ” is not [Rabin 1970].

Remark 3.13. The discussion above, concerning the property “on some path, p holds infinitely often” may be contrasted with the rather similar-looking formula $\psi := \mu x.\nu y.(\Diamond x \vee (\Diamond y \wedge p))$. This formula states that there is a path in which from a certain point on p always holds (“eventually always p ”). Syntactically, ψ is neither in $\mu_N\text{ML}$ (it has one alternation of fixpoints), nor a fortiori in $\mu_C\text{ML}$. However, it is not difficult to see that ψ is equivalent to the formula $\mu x.(\Diamond x \vee \nu y(\Diamond y \wedge p))$, which does belong to the continuous μ -calculus, and is in particular alternation free.

4. ONE-STEP LOGICS, PARITY AUTOMATA AND μ -CALCULI

This section introduces and studies the type of parity automata that will be used in the characterisation of WMSO and NMSO on tree models. In order to define these automata in a uniform way, we introduce, at a slightly higher level of abstraction, the notion of a *one-step logic*, a concept from coalgebraic modal logic [Cirstea and Pattinson 2004] which provides a nice framework for a general approach towards the theory of automata operating on infinite objects. As salient specimens of such one-step logics we will discuss monadic first-order logic with equality (FOE_1) and its extension with the infinity quantifier (FOE_1^∞). We then define, parametric in the language L_1 of such a one-step logic, the notions of an L_1 -automaton and of a mu-calculus μL_1 , and we show how various classes of L_1 -automata effectively correspond to fragments of μL_1 .

4.1. One-step logics and normal forms

Definition 4.1. Given a finite set A of monadic predicates, a *one-step model* is a pair (D, V) consisting of a *domain* set D and a *valuation* or *interpretation* $V : A \rightarrow \wp D$. Where $B \subseteq A$, we say that $V' : A \rightarrow \wp D$ is a *B-extension* of $V : A \rightarrow \wp D$, notation $V \leq_B V'$, if $V(b) \subseteq V'(b)$ for every $b \in B$ and $V(a) = V'(a)$ for every $a \in A \setminus B$.

A *one-step language* is a map assigning to any set A a collection $L_1(A)$ of objects that we will refer to as *one-step formulas* over A . We assume that one-step languages come with a *truth* relation \models between one-step formulas and models, writing $(D, V) \models \varphi$ to denote that (D, V) satisfies φ .

Note that we do allow the (unique) one-step model that is based on the empty domain; we will simply denote this model as (\emptyset, \emptyset) .

Our chief examples of one-step languages will be variations of modal and first-order logic.

Definition 4.2. For a set A of monadic predicates, the corresponding *basic one-step modal logic* $\text{ML}_1(A)$ is the language defined as:

$$\text{ML}_1(A) := \{\Diamond a, \Box a \mid a \in A\}.$$

The semantics of these formulas is given by

$$\begin{aligned} (D, V) \models \Diamond a & \quad \text{iff} \quad V(a) \neq \emptyset \\ (D, V) \models \Box a & \quad \text{iff} \quad V(a) = D. \end{aligned}$$

Definition 4.3. The one-step language $\text{FOE}_1(A)$ of *first-order logic with equality* on a set of predicates A and individual variables iVar is given by the sentences (formulas without free variables) generated by the following grammar, where $a \in A$ and $x, y \in \text{iVar}$:

$$\varphi ::= a(x) \mid \neg a(x) \mid x \approx y \mid x \not\approx y \mid \exists x. \varphi \mid \forall x. \varphi \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \quad (20)$$

We use FO_1 for the equality-free fragment, where we omit the clauses $x \approx y$ and $x \not\approx y$.

The interpretation of this language in a model (D, V) with $D \neq \emptyset$ is completely standard. Formulas of FO_1 and FOE_1 are interpreted inductively by augmenting the pair (D, V) with a variable assignment $g : \text{iVar} \rightarrow D$. The semantics then defines the desired truth relation $(D, V), g \models \varphi$ between one-step models, assignments and one-step formulas. As usual, the variable assignment g can and will be omitted when we are dealing with sentences — and note that we only take sentences as one-step formulas. For the interpretation in one-step models with empty domain we refer to Definition 4.5.

We now introduce an extension of first-order logic with two additional quantifiers, which first appeared in the context of Mostowski's study [Mostowski 1957] of generalised quantifiers. The first, written $\exists^\infty x. \varphi$, expresses that there exist infinitely many

elements satisfying a formula φ . Its dual, written $\forall^\infty x.\varphi$, expresses that there are *at most finitely many* elements *falsifying* the formula φ . Formally:

$$\begin{aligned} (D, V), g \models \exists^\infty x.\varphi(x) & \text{ iff } |\{s \in D \mid (D, V), g[x \mapsto s] \models \varphi(x)\}| \geq \omega \\ (D, V), g \models \forall^\infty x.\varphi(x) & \text{ iff } |\{s \in D \mid (D, V), g[x \mapsto s] \not\models \varphi(x)\}| < \omega \end{aligned} \quad (21)$$

Definition 4.4. The one-step language $\text{FOE}_1^\infty(A)$ is defined by adding to the grammar (20) of $\text{FOE}_1(A)$ the cases $\exists^\infty x.\varphi$ and $\forall^\infty x.\varphi$. In the case of non-empty models, the truth relation $(D, V), g \models \varphi$ is defined by extending the truth relation for $\text{FOE}_1(A)$ with the clauses (21).

In the case of models with empty domain, we cannot give an inductive definition of the truth relation using variable assignments. Nevertheless, a definition of truth can be provided for formulas that are Boolean combinations of sentences of the form $Qx.\varphi$, where $Q \in \{\exists, \exists^\infty, \forall, \forall^\infty\}$ is a quantifier.

Definition 4.5. For the empty one-step model (\emptyset, \emptyset) we define the truth relation as follows: For every sentence $Qx.\varphi$, where $Q \in \{\exists, \exists^\infty, \forall, \forall^\infty\}$, we set

$$\begin{aligned} (\emptyset, \emptyset) \not\models Qx.\varphi & \text{ if } Q \in \{\exists, \exists^\infty\} \\ (\emptyset, \emptyset) \models Qx.\varphi & \text{ if } Q \in \{\forall, \forall^\infty\}, \end{aligned}$$

and we extend this definition to arbitrary FOE_1^∞ -sentences via the standard clauses for the boolean connectives.

For various reasons it will be convenient to assume that our one-step languages are closed under taking (boolean) duals. Here we say that the one-step formulas φ and ψ are *boolean duals* if for every one-step model we have $(D, V) \models \varphi$ iff $(D, V^c) \not\models \psi$, where V^c is the complement valuation given by $V^c(a) := D \setminus V(a)$, for all a .

As an example, it is easy to see that for the basic one-step modal logic ML_1 the formulas $\Diamond a$ and $\Box a$ are each other's dual. In the case of the monadic predicate logics FO_1 , FOE_1 and FOE_1^∞ we can define the boolean dual of a formula φ by a straightforward induction.

Definition 4.6. For $L_1 \in \{\text{FO}_1, \text{FOE}_1, \text{FOE}_1^\infty\}$, we define the following operation on formulas:

$$\begin{aligned} (a(x))^\delta &:= a(x) & (\neg a(x))^\delta &:= \neg a(x) \\ (\top)^\delta &:= \perp & (\perp)^\delta &:= \top \\ (x \approx y)^\delta &:= x \not\approx y & (x \not\approx y)^\delta &:= x \approx y \\ (\varphi \wedge \psi)^\delta &:= \varphi^\delta \vee \psi^\delta & (\varphi \vee \psi)^\delta &:= \varphi^\delta \wedge \psi^\delta \\ (\exists x.\psi)^\delta &:= \forall x.\psi^\delta & (\forall x.\psi)^\delta &:= \exists x.\psi^\delta \\ (\exists^\infty x.\psi)^\delta &:= \forall^\infty x.\psi^\delta & (\forall^\infty x.\psi)^\delta &:= \exists^\infty x.\psi^\delta \end{aligned}$$

We leave it for the reader to verify that the operation $(\cdot)^\delta$ indeed provides a boolean dual for every one-step sentence.

The following semantic properties will be essential when studying the parity automata and μ -calculi associated with one-step languages.

Definition 4.7. Given a one-step language $L_1(A)$, $\varphi \in L_1(A)$ and $B \subseteq A$,

- φ is *monotone* in B if for all pairs of one step models (D, V) and (D, V') with $V \leq_B V'$, $(D, V) \models \varphi$ implies $(D, V') \models \varphi$.

- φ is *B-continuous* if φ is monotone in B and, whenever $(D, V) \models \varphi$, then there exists $V': A \rightarrow \wp(D)$ such that $V' \leq_B V$, $(D, V') \models \varphi$ and $V'(b)$ is finite for all $b \in B$.
- φ is *B-cocontinuous* if its dual φ^δ is continuous in B .

Example 4.8. Fix a set A of monadic predicates, a subset $B \subseteq A$ and a $b \in B$.

- (1) It is easy to see that a formula φ is monotone in B if all predicates from B occur only positively in φ (i.e., in the scope of an even number of negations). For simple formulas that are not monotone in b , consider for instance $\neg \exists x b(x)$ or $\forall x(a(x) \vee \neg b(x))$. On the other hand, the formula $\forall x(b(x) \vee \neg b(x))$, although it features a negative occurrence of b , is monotone in b .
- (2) Typical formulas that are continuous in b are $\exists x b(x)$ and $\exists x_1 \exists x_2 (x_1 \not\approx x_2 \wedge b(x_1) \wedge b(x_2))$. For a typical counterexample, take the formula $\forall x b(x)$.
- (3) Particularly interesting FOE_1^∞ -formulas that are continuous in B may be obtained using the abbreviated quantifier \mathbf{W} given by

$$\mathbf{W}x.(\varphi, \psi) := \forall x.(\varphi(x) \vee \psi(x)) \wedge \forall^\infty x.\psi(x). \quad (22)$$

In words, $\mathbf{W}x.(\varphi, \psi)$ states that every element of the domain validates $\varphi(x)$ or $\psi(x)$, but only finitely many need to validate $\varphi(x)$. As a consequence, if φ is continuous in B , and no $b \in B$ occurs in ψ , then the formula $\mathbf{W}x.(\varphi, \psi)$ will be continuous in B . Thus \forall^∞ makes a certain use of the universal quantifier compatible with the notion of continuity.

We recall from [Carreiro et al. 2018] syntactic characterisations of these semantic properties, relative to the monadic predicate logics FO_1 , FOE_1 and FOE_1^∞ . We first discuss characterisations of monotonicity and (co)continuity given by grammars.

Definition 4.9. For $L_1 \in \{\text{FO}_1, \text{FOE}_1, \text{FOE}_1^\infty\}$, we define the *positive* fragment of $L_1(A)$, written $L_1^+(A)$, as the set of sentences generated by the grammar we obtain by leaving out the clause $\neg a(x)$ from the grammar for L_1 .

For $B \subseteq A$, the *B-continuous* fragment of $\text{FOE}_1(A)$, written $\text{Con}_B(\text{FOE}_1(A))$, is the set of sentences generated by the following grammar:

$$\varphi ::= b(x) \mid \psi \mid \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \exists x.\varphi, \quad (23)$$

for $b \in B$ and $\psi \in \text{FOE}_1^+(A \setminus B)$. When $\psi \in \text{FO}_1^+(A \setminus B)$, the grammar (23) above generates the *B-continuous* fragment $\text{Con}_B(\text{FO}_1(A))$ of $\text{FO}_1(A)$. Finally, the *B-continuous* fragment of $\text{FOE}_1^\infty(A)$, written $\text{Con}_B(\text{FOE}_1^\infty(A))$, is generated as follows:

$$\varphi ::= b(x) \mid \psi \mid \varphi \wedge \varphi \mid \varphi \vee \varphi \mid \exists x.\varphi \mid \mathbf{W}x.(\varphi, \psi), \quad (24)$$

where $b \in B$, $\psi \in (\text{FOE}_1^\infty)^+(A \setminus B)$, and $\mathbf{W}x.(\varphi, \psi)$ is defined as in (22).

For $L_1 \in \{\text{FO}_1, \text{FOE}_1, \text{FOE}_1^\infty\}$ and $B \subseteq A$, the *B-cocontinuous* fragment of $L_1(A)$, written $\text{CoCon}_B(L_1(A))$, is the set $\{\varphi \mid \varphi^\delta \in \text{Con}_B(L_1(A))\}$.

Note that we do allow the clause $x \not\approx y$ in the positive fragments of FOE_1 and FOE_1^∞ .

The following result provides syntactic characterizations for the mentioned semantics properties.

THEOREM 4.10 ([CARREIRO ET AL. 2018]). For $L_1 \in \{\text{FO}_1, \text{FOE}_1, \text{FOE}_1^\infty\}$, let $\varphi \in L_1(A)$ be a one-step formula. Then

- (1) $\varphi \in L_1(A)$ is *A-monotone* iff it is equivalent to some $\psi \in L_1^+(A)$.
- (2) $\varphi \in L_1(A)$ is *B-continuous* iff it is equivalent to some $\psi \in \text{Con}_B(L_1(A))$.
- (3) $\varphi \in L_1(A)$ is *B-cocontinuous* iff it is equivalent to some $\psi \in \text{CoCon}_B(L_1(A))$.

PROOF. The first two statements are proved in [Carreiro et al. 2018]. The third one can be verified by a straightforward induction on φ . \square

In some of our later proofs we need more precise information on the shape of formulas belonging to certain syntactic fragments. For this purpose we introduce normal forms for positive sentences in FO_1 , FOE_1 and FOE_1^∞ .

Definition 4.11. A type T is just a subset of A . It defines a FOE_1 -formula

$$\tau_T^+(x) := \bigwedge_{a \in T} a(x).$$

Given a one-step model (D, V) , $s \in D$ witnesses a type T if $(D, V), g[x \mapsto s] \models \tau_T^+(x)$ for **some (or, equivalently, each) assignment** g . The predicate $\text{diff}(\bar{y})$, stating that the elements \bar{y} are distinct, is defined as $\text{diff}(y_1, \dots, y_n) := \bigwedge_{1 \leq m < m' \leq n} (y_m \not\approx y_{m'})$.

A formula $\varphi \in \text{FO}_1(A)$ is said to be in **basic form** if it is of the shape $\varphi = \bigvee \nabla_{\text{FO}}^+(\Sigma, \Pi)$, where for sets $\Sigma, \Pi \subseteq A$ of types, the formula $\nabla_{\text{FO}}^+(\Sigma, \Pi) \in \text{FO}_1(A)$ is defined as

$$\nabla_{\text{FO}}^+(\Sigma, \Pi) := \bigwedge_{S \in \Sigma} \exists x \tau_S^+(x) \wedge \forall z. \bigvee_{S \in \Pi} \tau_S^+(z).$$

We say that $\varphi \in \text{FOE}_1(A)$ is in **basic form** if it is a disjunction of formulas of the form $\nabla_{\text{FOE}}^+(\bar{\mathbf{T}}, \Pi)$, where each disjunct is of the form

$$\nabla_{\text{FOE}}^+(\bar{\mathbf{T}}, \Pi) := \exists \bar{x}. (\text{diff}(\bar{x}) \wedge \bigwedge_i \tau_{T_i}^+(x_i) \wedge \forall z. (\text{diff}(\bar{x}, z) \rightarrow \bigvee_{S \in \Pi} \tau_S^+(z)))$$

such that $\bar{\mathbf{T}} = (T_1, \dots, T_k) \in \wp(A)^k$ for some k and $\Pi \subseteq \{T_1, \dots, T_k\}$.

Finally, we say that $\varphi \in \text{FOE}_1^\infty(A)$ is in **basic form** if it is a disjunction of formulas of the form $\nabla_{\text{FOE}^\infty}^+(\bar{\mathbf{T}}, \Pi, \Sigma)$, where each disjunct is of the form

$$\begin{aligned} \nabla_{\text{FOE}^\infty}^+(\bar{\mathbf{T}}, \Pi, \Sigma) &:= \nabla_{\text{FOE}}^+(\bar{\mathbf{T}}, \Pi \cup \Sigma) \wedge \nabla_\infty^+(\Sigma) \\ \nabla_\infty^+(\Sigma) &:= \bigwedge_{S \in \Sigma} \exists^\infty y. \tau_S^+(y) \wedge \forall^\infty y. \bigvee_{S \in \Sigma} \tau_S^+(y) \end{aligned}$$

for some sets of types $\Pi, \Sigma \subseteq \wp A$ and $T_1, \dots, T_k \subseteq A$.

Intuitively, the basic FO_1 -formula $\nabla_{\text{FO}}^+(\Sigma, \Pi)$ simply states that every type $S \in \Sigma$ is witnessed in the model and at the same time, every element of the domain witnesses some type in Π .³ The formula $\nabla_{\text{FOE}}^+(\bar{\mathbf{T}}, \Pi)$ says that each one-step model satisfying it admits a partition of its domain in two parts: distinct elements t_1, \dots, t_n witnessing types T_1, \dots, T_n , and all the remaining elements witnessing some type S of Π . The formula $\nabla_\infty^+(\Sigma)$ extends the information given by $\nabla_{\text{FOE}}^+(\bar{\mathbf{T}}, \Pi \cup \Sigma)$ by saying that (1) for every type $S \in \Sigma$, there are infinitely many elements witnessing each $S \in \Sigma$ and (2) only finitely many elements do not satisfy any type in Σ .

The next theorem states that the basic formulas indeed provide normal forms.

THEOREM 4.12 ([CARREIRO ET AL. 2018]). *For each $L_1 \in \{\text{FO}_1, \text{FOE}_1, \text{FOE}_1^\infty\}$ there is an effective procedure transforming any sentence $\varphi \in L_1^+(A)$ into an equivalent sentence φ^\bullet in basic L_1 -form.*

³In fact, it is not hard to show that every formula of the form $\nabla_{\text{FO}}^+(\Sigma, \Pi)$ is equivalent to a disjunction of formulas of the form $\nabla_{\text{FO}}^+(\Gamma, \Gamma)$, which are closely related to the disjunctive formulas that feature in the work of Janin and Walukiewicz. In principle we could simplify our basic FO_1 -form further, to formulas of the form $\nabla_{\text{FO}}^+(\Gamma, \Gamma)$; for the characterisation of continuity in Theorem 4.13, however, this format is not suitable.

One may use these normal forms to provide a tighter syntactic characterisation for the notion of continuity, in the cases of FO_1 and FOE_1^∞ .

THEOREM 4.13 ([CARREIRO ET AL. 2018]).

- (1) A formula $\varphi \in \text{FO}_1(A)$ is continuous in $B \subseteq A$ iff it is equivalent to a formula, effectively obtainable from φ , in the basic form $\bigvee \nabla_{\text{FO}}^+(\Sigma, \Pi)$ where we require that $B \cap \bigcup \Pi = \emptyset$ for every Π .
- (2) A formula $\varphi \in \text{FOE}_1^\infty(A)$ is continuous in $B \subseteq A$ iff it is equivalent to a formula, effectively obtainable from φ , in the basic form $\bigvee \nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma)$, where we require that $B \cap \bigcup \Sigma = \emptyset$ for every Σ .

Remark 4.14. We focussed on normal form results for monotone and (co)continuous sentences, as these are the ones relevant to our study of parity automata. However, generic sentences both of FO_1 , FOE_1 and FOE_1^∞ also enjoy normal form results, with the syntactic formats given by variations of the “basic form” above. The interested reader may find in [Carreiro et al. 2018] a detailed overview of these results.

We finish this section with a discussion of the notion of *separation*.

Definition 4.15. Fix a one-step language L_1 , and two sets A and B with $B \subseteq A$. Given a one-step model (D, V) , we say that $V : A \rightarrow \wp D$ *separates* B if $|V^{-1}(d) \cap B| \leq 1$, for every $d \in D$, where $V^{-1}(d) = \{a \in A \mid d \in V(a)\}$. A formula $\varphi \in L_1(A)$ is *B-separating* if φ is monotone in B and, whenever $(D, V) \models \varphi$, then there exists a B -separating valuation $V' : A \rightarrow \wp(D)$ such that $V' \leq_B V$ and $(D, V') \models \varphi$.

Intuitively, a formula φ is B -separating if its truth in a one-step model never requires an element of the domain to satisfy two distinct predicates in B at the same time.

Example 4.16. Let A be a set of monadic predicates and let $B = \{b_1, b_2\} \subseteq A$.

- (1) A typical example of a formula that is *not* B -separating is $\exists x b_1 \wedge \forall y b_2(y)$. The point is that any one-step model satisfying this formula will have at least one element satisfying both b_1 and b_2 . As another example of a formula that is *not* B -separating, take $\varphi := \exists x b_1(x) \wedge \exists x b_2(x)$. This formula is in fact easily satisfiable in a B -separating model, but if we consider a model (D, V) for φ in which there is a element d such that $V(b_1) = V(b_2) = \{d\}$, then we cannot shrink V to a B -separating valuation V' such that $(D, V') \models \varphi$.
- (2) For an example of a formula that is B -separating, consider the formula $\exists x_1 \exists x_2 (x_1 \not\approx x_2 \wedge b(x_1) \wedge b(x_2))$. This example is generalised in Proposition 4.17.

We do not need a full syntactic characterisation of this notion, but the following sufficient condition is used later on.

PROPOSITION 4.17.

- (1) Let $\varphi \in \text{FOE}_1^+(A)$ be a formula in basic form, $\varphi = \bigvee \nabla_{\text{FOE}}^+(\overline{\mathbf{T}}, \Pi)$. Then φ is B -separating if, for each disjunct, $|S \cap B| \leq 1$ for each $S \in \{T_1, \dots, T_k\} \cup \Pi$.
- (2) Let $\varphi \in \text{FOE}_1^{\infty+}(A)$ be a formula in basic form, $\varphi = \bigvee \nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma)$. Then φ is B -separating if, for each disjunct, $|S \cap B| \leq 1$ for each $S \in \{T_1, \dots, T_k\} \cup \Pi \cup \Sigma$.

PROOF. We only discuss the case $L_1 = \text{FOE}_1^\infty$: a simplification of the same argument yields the case $L_1 = \text{FOE}_1$. Assume that $(D, V) \models \varphi$ for some model (D, V) . We want to construct a valuation $V' \leq_B V$ witnessing the B -separation property. First, we fix one disjunct $\psi = \nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma)$ of φ such that $(D, V) \models \psi$. The syntactic shape of ψ implies that (D, V) can be partitioned in three sets D_1 , D_2 and D_3 as follows: D_1

contains elements s_1, \dots, s_k witnessing types T_1, \dots, T_k , respectively; among the remaining elements, there are infinitely many witnessing some $S \in \Sigma$ (these form D_2), and finitely many not witnessing any $S \in \Sigma$ but each witnessing some $R \in \Pi$ (these form D_3). In other words, we have assigned to each $d \in D$ a type $S_d \in \{T_1, \dots, T_k\} \cup \Pi \cup \Sigma$ such that d witnesses S_d . Now consider the valuation U that we obtain by pruning V to the extent that $U(a) := V(a)$ for $a \in A \setminus B$, while $U(b) := \{d \in D \mid b \in S_d\}$. It is then easy to see that we still have $(D, U) \models \psi$, while it is obvious that U separates B and that $U \leq_B A$. Therefore ψ is B -separating and so φ is too. \square

4.2. Parity automata

Throughout the rest of the section we fix, next to a set P of proposition letters, a one-step language L_1 , as defined in Subsection 4.1. In addition, we assume that we have isolated fragments $L_1^+(A)$, $\text{Con}_B(L_1(A))$ and $\text{CoCon}_B(L_1(A))$ consisting of one-step formulas in $L_1(A)$ that are respectively monotone, B -continuous and B -co-continuous, for $B \subseteq A$.

We first recall the definition of a general parity automaton, adapted to this setting.

Definition 4.18 (Parity Automata). A parity automaton based on the one-step language L_1 and the set P of proposition letters, or briefly: an L_1 -automaton, is a tuple $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ such that A is a finite set of states, also called the *carrier of \mathbb{A}* , $a_I \in A$ is the initial state, $\Delta : A \times \wp(P) \rightarrow L_1^+(A)$ is the transition map, and $\Omega : A \rightarrow \mathbb{N}$ is the priority map. The class of such automata will be denoted by $\text{Aut}(L_1)$.

Acceptance of a P -transition system $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ by \mathbb{A} is determined by the *acceptance game* $\mathcal{A}(\mathbb{A}, \mathbb{S})$ of \mathbb{A} on \mathbb{S} . This is the parity game defined according to the rules of the following table.

Position	Player	Admissible moves	Priority
$(a, s) \in A \times T$	\exists	$\{V : A \rightarrow \wp(R[s]) \mid (R[s], V) \models \Delta(a, \kappa(s))\}$	$\Omega(a)$
$V : A \rightarrow \wp(T)$	\forall	$\{(b, t) \mid t \in V(b)\}$	0

\mathbb{A} *accepts* \mathbb{S} if \exists has a winning strategy in $\mathcal{A}(\mathbb{A}, \mathbb{S}) @ (a_I, s_I)$, and *rejects* \mathbb{S} if (a_I, s_I) is a winning position for \forall . We write $\text{Mod}(\mathbb{A})$ for the class of transition systems that are accepted by \mathbb{A} and $\text{TMod}(\mathbb{A})$ for the class of tree models in $\text{Mod}(\mathbb{A})$.

Explained in words, the acceptance game $\mathcal{A}(\mathbb{A}, \mathbb{S})$ proceeds in rounds, each round moving from one basic position $(a, s) \in A \times T$ to the next. At such a basic position, it is \exists 's task to turn the set $R(s)$ of successors of s into the domain of a one-step model for the formula $\Delta(a, \kappa(s)) \in L_1(A)$. That is, she needs to come up with a valuation $V : A \rightarrow \wp(R[s])$ such that $(R[s], V) \models \Delta(a, \kappa(s))$ (and if she cannot find such a valuation, she loses immediately). One may think of the set $\{(b, t) \mid t \in V(b)\}$ as a collection of witnesses to her claim that, indeed, $(R[s], V) \models \Delta(a, \kappa(s))$. The round ends with \forall picking one of these witnesses, which then becomes the basic position at the start of the next round. (Unless, of course, \exists managed to satisfy the formula $\Delta(a, \kappa(s))$ with an empty set of witnesses, in which case \forall gets stuck and loses immediately.)

Many properties of parity automata can already be determined at the one-step level. An important example concerns the notion of complementation, which will be used later in this section. Recall the notion of (Boolean) *dual* of a one-step formula (Definition 4.1). Following ideas from [Muller and Schupp 1987; Kissig and Venema 2009], we can use duals, together with a *role switch* between \forall and \exists , in order to define a negation or complementation operation on automata.

Definition 4.19. Assume that, for some one-step language L_1 , the map $(\cdot)^\delta$ provides, for each set A , a Boolean dual $\varphi^\delta \in L_1(A)$ for each $\varphi \in L_1(A)$. We define the *complement*

of a given L_1 -automaton $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ as the automaton $\mathbb{A}^\delta := \langle A, \Delta^\delta, \Omega^\delta, a_I \rangle$ where $\Delta^\delta(a, c) := (\Delta(a, c))^\delta$, and $\Omega^\delta(a) := 1 + \Omega(a)$, for all $a \in A$ and $c \in \wp(P)$.

PROPOSITION 4.20. *Let L_1 and $(\cdot)^\delta$ be as in the previous definition. For each $\mathbb{A} \in \text{Aut}(L_1)$ and \mathbb{S} we have that \mathbb{A}^δ accepts \mathbb{S} if and only if \mathbb{A} rejects \mathbb{S} .*

The proof of Proposition 4.20 is based on the fact that the *power* of \exists in $\mathcal{A}(\mathbb{A}^\delta, \mathbb{S})$ is the same as that of \forall in $\mathcal{A}(\mathbb{A}, \mathbb{S})$, as defined in [Kissig and Venema 2009]. As an immediate consequence, one may show that if the one-step language L_1 is closed under duals, then the class $\text{Aut}(L_1)$ is closed under taking complementation. Further on we will use Proposition 4.20 to show that the same may apply to some subclasses of $\text{Aut}(L_1)$.

The automata-theoretic characterisation of WMSO and NMSO will use classes of parity automata constrained by two additional properties. To formulate these we first introduce the notion of a *cluster*.

Definition 4.21. Let L_1 be a one-step language, and let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be in $\text{Aut}(L_1)$. Write \prec for the reachability relation in \mathbb{A} , i.e., the transitive closure of the “occurrence relation” $\{(a, b) \mid b \text{ occurs in } \Delta(a, c) \text{ for some } c \in \wp(P)\}$; in case $a \prec b$ we say that b is *active* in a . A *cluster* of \mathbb{A} is a cell of the equivalence relation generated by the relation $\prec \cap \succ$ (i.e., the intersection of \prec with its converse). A cluster is called *degenerate* if it consists of a single element which is not active in itself.

Remark 4.22. Observe that any cluster of an automaton is either degenerate, or else each of its states is active in itself and in any other state of the cluster. Observe too that there is a natural order on clusters: we may say that one cluster is *higher* than another if each member of the second cluster is active in each member of the first. We may assume without loss of generality that the initial state belongs to the highest cluster of the automaton.

We can now formulate the mentioned requirements on L_1 -automata as follows.

Definition 4.23. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be some L_1 -automaton. We say that \mathbb{A} is *weak* if $\Omega(a) = \Omega(b)$ whenever a and b belong to the same cluster. For the property of *continuity* we require that, for any cluster M , any state $a \in M$ and any $c \in \wp(P)$, we have that $\Omega(a) = 1$ implies $\Delta(a, c) \in \text{Con}_M(L_1(A))$ and $\Omega(a) = 0$ implies $\Delta(a, c) \in \text{CoCon}_M(L_1(A))$.

We call a parity automaton $\mathbb{A} \in \text{Aut}(L_1)$ *weak-continuous* if it satisfies both properties, weakness and continuity. The classes of weak and weak-continuous automata are denoted as $\text{Aut}_w(L_1)$ and $\text{Aut}_{wc}(L_1)$, respectively.

Intuitively, weakness forbids an automaton to register **non-trivial** properties concerning the vertical ‘dimension’ of input trees **such as “there is a path in which infinitely many nodes satisfy p ”**, whereas continuity expresses a constraint on how much of the horizontal ‘dimension’ of an input tree the automaton is allowed to process. In terms of second-order logic, they correspond respectively to quantification over ‘vertically’ finite (i.e. included in well-founded subtrees) and ‘horizontally’ finite (i.e. included in finitely branching subtrees) sets. The conjunction of weakness and continuity thus corresponds to quantification over finite sets.

Remark 4.24. Any weak parity automaton \mathbb{A} is equivalent to a special weak automaton \mathbb{A}' with $\Omega : A' \rightarrow \{0, 1\}$. This is because (*weakness*) prevents states of different parity to occur infinitely often in acceptance games; so we may just replace any even priority with 0, and any odd priority with 1. We shall assume such a restricted priority map for weak parity automata.

4.3. μ -Calculi

We now see how to associate, with each one-step language L_1 , the following variant μL_1 of the modal μ -calculus. These logics are of a fairly artificial nature; their main use is to smoothen the translations from automata to second-order formulas further on.

Definition 4.25. Given a one-step language L_1 , we define the language μL_1 of the μ -calculus over L_1 by the following grammar:

$$\varphi ::= q \mid \neg q \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) \mid \mu p. \varphi' \mid \nu p. \varphi',$$

where $p, q \in \text{Prop}$, $\alpha(a_1, \dots, a_n) \in L_1^+$ and φ' is monotone in p .

As in the case of the modal μ -calculus μML , we will freely use standard syntactic concepts and notations related to this language.

Observe that the language μL_1 generally has a wealth of modalities: one for each one-step formula in L_1 .

The semantics of this language is given as follows.

Definition 4.26. Let \mathbb{S} be a transition system. The satisfaction relation \models is defined in the standard way, with the following clause for the modality \bigcirc_α :

$$\mathbb{S} \models \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) \quad \text{iff} \quad (R[s_I], V_{\overline{\varphi}}) \models \alpha(a_1, \dots, a_n), \quad (25)$$

where $V_{\overline{\varphi}}$ is the one-step valuation given by

$$V_{\overline{\varphi}}(a_i) := \{t \in R[s_I] \mid \mathbb{S}.t \models \varphi_i\}. \quad (26)$$

Example 4.27.

- (1) If we identify the modalities $\bigcirc_{\diamond a}$ and $\bigcirc_{\square a}$ of the basic modal one-step language ML_1 (cf. Definition 4.2) with the standard \diamond and \square operators, we may observe that $\mu(\text{ML}_1)$ corresponds to the standard modal μ -calculus: $\mu(\text{ML}_1) = \mu\text{ML}$.
- (2) Consider the one-step formulas $\alpha = \exists x(a_1(x) \wedge \forall y a_2(y))$, $\beta = \exists xy(x \not\approx y \wedge a_1(x) \wedge a_1(y))$, and $\gamma = \text{W}x(a_1(x), a_2(x))$. Then $\bigcirc_\alpha(\varphi_1, \varphi_2)$ is equivalent to the modal formula $\diamond \varphi_1 \wedge \square \varphi_2$ and $\bigcirc_\beta(\varphi)$ expresses that the current state has at least two successors where φ holds. The formula $\bigcirc_\gamma(\varphi_1, \varphi_2)$ holds at a state s if all its successors satisfy φ_1 or φ_2 , while at most finitely many successors refute φ_2 . Neither \bigcirc_β nor \bigcirc_γ can be expressed in standard modal logic.
- (3) If the one-step language L_1 is closed under taking disjunctions (conjunctions, respectively), it is easy to see that $\bigcirc_{\alpha \vee \beta}(\overline{\varphi}) \equiv \bigcirc_\alpha(\overline{\varphi}) \vee \bigcirc_\beta(\overline{\varphi})$ ($\bigcirc_{\alpha \wedge \beta}(\overline{\varphi}) \equiv \bigcirc_\alpha(\overline{\varphi}) \wedge \bigcirc_\beta(\overline{\varphi})$, respectively).

Alternatively but equivalently, one may interpret the language game-theoretically.

Definition 4.28. Given a μL_1 -formula φ and a model \mathbb{S} we define the *evaluation game* $\mathcal{E}(\varphi, \mathbb{S})$ as the two-player infinite game whose rules are given in the next table.

Position	Player	Admissible moves
(q, s) , with $q \in FV(\varphi) \cap \kappa(s)$	\forall	\emptyset
(q, s) , with $q \in FV(\varphi) \setminus \kappa(s)$	\exists	\emptyset
$(\neg q, s)$, with $q \in FV(\varphi) \cap \kappa(s)$	\exists	\emptyset
$(\neg q, s)$, with $q \in FV(\varphi) \setminus \kappa(s)$	\forall	\emptyset
$(\psi_1 \vee \psi_2, s)$	\exists	$\{(\psi_1, s), (\psi_2, s)\}$
$(\psi_1 \wedge \psi_2, s)$	\forall	$\{(\psi_1, s), (\psi_2, s)\}$
$(\bigcirc_\alpha(\varphi_1, \dots, \varphi_n), s)$	\exists	$\{Z \subseteq \{\varphi_1, \dots, \varphi_n\} \times R[s] \mid (R[s], V_Z^*) \models \alpha(\bar{a})\}$
$Z \subseteq Sfor(\varphi) \times S$	\forall	$\{(\psi, s) \mid (\psi, s) \in Z\}$
$(\mu p.\varphi, s)$	$-$	$\{(\varphi, s)\}$
$(\nu p.\varphi, s)$	$-$	$\{(\varphi, s)\}$
(p, s) , with $p \in BV(\varphi)$	$-$	$\{(\delta_p, s)\}$

For the admissible moves at a position of the form $(\bigcirc_\alpha(\varphi_1, \dots, \varphi_n), s)$, we consider the valuation $V_Z^* : \{a_1, \dots, a_n\} \rightarrow \varphi(R[s])$, given by $V_Z^*(a_i) := \{t \in R[s] \mid (\varphi_i, t) \in Z\}$. The winning conditions of $\mathcal{E}(\varphi, \mathbb{S})$ are standard: \exists wins those infinite matches of which the highest variable that is unfolded infinitely often during the match is a μ -variable.

The following proposition, stating the adequacy of the evaluation game for the semantics of μL_1 , is formulated explicitly for future reference. We omit the proof, which is completely routine.

FACT 4.29 (ADEQUACY). *For any formula $\varphi \in \mu L_1$ and any model \mathbb{S} the following equivalence holds:*

$$\mathbb{S} \models \varphi \text{ iff } (\varphi, s_I) \text{ is a winning position for } \exists \text{ in } \mathcal{E}(\varphi, \mathbb{S}).$$

We will be specifically interested in two fragments of μL_1 , associated with the properties of being noetherian and continuous, respectively, and with the associated variants of the μ -calculus μL_1 where the use of the fixpoint operator μ is restricted to formulas belonging to these two respective fragments.

Definition 4.30. Let Q be a set of proposition letters. We first define the fragment $\text{Noe}_Q(\mu L_1)$ of μL_1 of formulas that are syntactically *noetherian* in Q by the following grammar:

$$\varphi ::= q \mid \psi \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) \mid \mu p.\varphi'$$

where $q \in Q$, ψ is a Q -free μML -formula, $\alpha(a_1, \dots, a_n) \in L_1^+$ and $\varphi' \in \text{Noe}_{Q \cup \{p\}}(\mu L_1)$. The *co-noetherian* fragment $\text{CoNoe}_Q(\mu L_1)$ is defined dually.

Similarly, we define the fragment $\text{Con}_Q(\mu L_1)$ of μL_1 -formulas that are syntactically *continuous* in Q as follows:

$$\varphi ::= q \mid \psi \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \bigcirc_\alpha(\varphi_1, \dots, \varphi_k, \psi_1, \dots, \psi_m) \mid \mu p.\varphi'$$

where $p \in \text{Prop}$, $q \in Q$, ψ, ψ_i are Q -free μL_1 -formula, $\alpha(a_1, \dots, a_k, b_1, \dots, b_m) \in \text{Con}_{\bar{a}}(L_1)(\bar{a}, \bar{b})$, and $\varphi' \in \text{Con}_{Q \cup \{p\}}(\mu L_1)$. The *co-continuous* fragment $\text{CoCon}_Q(\mu L_1)$ is defined dually.

Based on this we can now define the mentioned variants of the μ -calculus μL_1 where the use of the least (greatest) fixpoint operator can only be applied to formulas that belong to, respectively, the noetherian (co-noetherian) and continuous (co-continuous) fragment of the language that we are defining.

Definition 4.31. The formulas of the *alternation-free* μ -calculus $\mu_N L_1$ are defined by the following grammar:

$$\varphi ::= q \mid \neg q \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) \mid \mu p.\varphi' \mid \nu p.\varphi'',$$

where $\alpha(a_1, \dots, a_n) \in L_1^+$, $\varphi' \in \mu_N L_1 \cap \text{Noe}_p(\mu L_1)$ and dually $\varphi'' \in \mu_N L_1 \cap \text{CoNoe}_p(\mu L_1)$.

Similarly, the formulas of the *continuous* μ -calculus $\mu_C L_1$ are given by the grammar

$$\varphi ::= q \mid \neg q \mid \varphi \vee \varphi \mid \varphi \wedge \varphi \mid \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) \mid \mu p. \varphi' \mid \nu p. \varphi'',$$

where $\alpha(a_1, \dots, a_n) \in L_1^+$, $\varphi' \in \mu_C L_1 \cap \text{Con}_p(\mu L_1)$ and dually $\varphi'' \in \mu_C L_1 \cap \text{CoCon}_p(\mu L_1)$.

Example 4.32. Following up on Example 4.27, it is easy to verify that $\mu_N \text{ML}_1 = \mu_N \text{ML}$ and $\mu_C \text{ML}_1 = \mu_C \text{ML}$.

4.4. From automata to fixpoint formulas and back

In the context of modal fixpoint logics and automata operating on (possibly) infinite objects, it is well-known that there are effective translations from parity automata to fixpoint formulas and vice versa [Grädel et al. 2002]. The results on L_1 -automata that we need in this paper are the following.

THEOREM 4.33. *There is an effective procedure that, given an automaton \mathbb{A} in $\text{Aut}(L_1)$, returns a formula $\xi_{\mathbb{A}} \in \mu L_1$ which satisfies the following properties:*

- (1) $\xi_{\mathbb{A}}$ is equivalent to \mathbb{A} ;
- (2) $\xi_{\mathbb{A}} \in \mu_N L_1$ if $\mathbb{A} \in \text{Aut}_w(L_1)$;
- (3) $\xi_{\mathbb{A}} \in \mu_C L_1$ if $\mathbb{A} \in \text{Aut}_{wc}(L_1)$.

THEOREM 4.34. *Let L_1 be a on-step language that is closed under taking conjunctions and disjunctions. Then there is an effective procedure that, given a formula $\xi \in \mu L_1$ returns an automaton \mathbb{A}_{ξ} in $\text{Aut}(L_1)$, which satisfies the following properties:*

- (1) \mathbb{A}_{ξ} is equivalent to ξ ;
- (2) $\mathbb{A}_{\xi} \in \text{Aut}_w(L_1)$ if $\xi \in \mu_N L_1$;
- (3) $\mathbb{A}_{\xi} \in \text{Aut}_{wc}(L_1)$ if $\xi \in \mu_C L_1$.

For both theorems, the first item can be proved by standard methods. In order to prove the second and third items, some care is needed to ensure that the translation obtained in the proof of the first item, lands in the right fragment of the language, respectively, produces an automaton of the right kind. In both cases, these proofs are not entirely trivial, they are fairly straightforward, and certainly rather tedious. For this reason we refer the interested reader to the technical report for the details.

5. AUTOMATA FOR WMSO

In this section we start looking at the automata-theoretic characterisation of WMSO. That is, we introduce the following automata, corresponding to this version of monadic second-order logic; these WMSO-*automata* are the continuous-weak automata for the one-step language FOE_1^∞ , cf. Definition 4.23.

Definition 5.1. A WMSO-*automaton* is a continuous-weak automaton for the one-step language FOE_1^∞ .

Recall that our definition of continuous-weak automata is syntactic in nature, i.e., if $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ is a WMSO-automaton, then for any pair of states a, b with $a \prec b$ and $b \prec a$, and any $c \in C$, we have $\Delta(a, c) \in \text{Con}_b(\text{FOE}_1^\infty(A)^+)$ if $\Omega(a)$ is odd and $\Delta(a, c) \in \text{CoCon}_b(\text{FOE}_1^\infty(A)^+)$ if $\Omega(a)$ is even.

The main result of this section states one direction of the automata-theoretic characterisation of WMSO.

THEOREM 5.2. *There is an effective construction transforming a WMSO-formula φ into a WMSO-automaton \mathbb{A}_φ that is equivalent to φ on the class of trees.*

The proof of Theorem 5.2, provided at the end of this section, proceeds by induction on the complexity of φ . The case $\varphi = \exists p.\psi$ requires most of the work. First, we need to define a closure operation on classes of tree models corresponding to the semantics of WMSO quantification.

Definition 5.3. Fix a set P of proposition letters, a proposition letter $p \notin P$ and a language C of $P \cup \{p\}$ -labeled trees. The *finitary projection* of C over p is the language of P -labeled trees defined as

$$\exists_F p.C := \{\mathbb{T} \mid \text{there is a finite } p\text{-variant } \mathbb{T}' \text{ of } \mathbb{T} \text{ with } \mathbb{T}' \in C\}.$$

A collection of classes of tree models is *closed under finitary projection over p* if it contains the class $\exists_F p.C$ whenever it contains the class C itself.

The case $\varphi = \exists p.\psi$ of the proof of Theorem 5.2 will require a *projection construction* that, given a WMSO-automaton \mathbb{A} , provides one recognising $\exists_F p.\text{TMod}(\mathbb{A})$. In other words, this will prove that the collection of classes that are recognisable by WMSO-automata is closed under finitary projection. The next subsection is devoted to a preliminary result, allowing to put WMSO-automata in a suitable shape for the projection construction.

5.1. Simulation theorem for WMSO-automata

For SMSO-automata, the analogous projection construction ([mimicking SMSO quantification](#)) crucially uses the following *simulation theorem*: every SMSO-automaton \mathbb{A} is equivalent to a *non-deterministic* automaton \mathbb{A}' [Walukiewicz 1996]. Semantically, non-determinism yields the appealing property that every node of the input model \mathbb{T} is associated with at most one state of \mathbb{A}' during the acceptance game—that means, we may assume \exists 's strategy f in $\mathcal{A}(\mathbb{A}', \mathbb{T})$ to be *functional* (cf. Definition 5.9 below). This is particularly helpful in case we want to define a p -variant of \mathbb{T} that is accepted by the projection construct on \mathbb{A}' : our decision whether to label a node s with p or not, will crucially depend on the value $f(a, s)$, where a is the unique state of \mathbb{A}' that is associated with s . Now, in the case of WMSO-automata we are interested in guessing *finitary* p -variants, which requires f to be functional only on a *finite* set of nodes. Thus the idea of our simulation theorem is to turn a WMSO-automaton \mathbb{A} into an equivalent device \mathbb{A}^F that consists of an initial, non-deterministic part, together with a final part which

is a copy of the (generally alternating) automaton \mathbb{A} itself; in this way we can make sure that \mathbb{A}^F behaves non-deterministically on a *finite* part of any accepted tree.

For SMSO-automata, the simulation theorem is based on a powerset construction: if the starting automaton has set of states A , the resulting non-deterministic automaton is based on “macro-states” from the set $\wp A$. Analogously, for WMSO-automata we will associate the non-deterministic behaviour with macro-states. However, as explained above, the automaton \mathbb{A}^F that we construct has to be non-deterministic just on finitely many nodes of the input and may behave as \mathbb{A} (i.e. in “alternating mode”) on the others. To this aim, \mathbb{A}^F will be “two-sorted”, roughly consisting of a copy of \mathbb{A} (with set of states A) together with a variant of its powerset construction, based both on A and $\wp A$. For any accepted \mathbb{T} , the idea is to make any match π of $\mathcal{A}(\mathbb{A}^F, \mathbb{T})$ consist of two parts:

- (*Non-deterministic mode*). For finitely many rounds π is played on macro-states, i.e. positions belong to the set $\wp A \times T$. In her strategy player \exists assigns macro-states (from $\wp A$) only to *finitely many* nodes, and states (from A) to the rest. Also, her strategy is functional in $\wp A$, i.e. it assigns at *most one macro-state* to each node.
- (*Alternating mode*). At a certain round, π abandons macro-states and turns into a match of the game $\mathcal{A}(\mathbb{A}, \mathbb{T})$, i.e. all subsequent positions are from $A \times T$ (and are played according to a not necessarily functional strategy).

Therefore successful runs of \mathbb{A}^N will have the property of processing only a *finite* amount of the input with \mathbb{A}^N being in a macro-state and all the rest with \mathbb{A}^N behaving exactly as \mathbb{A} . We now proceed in steps towards the construction of \mathbb{A}^N . First, recall from Definition 4.11 that an *A-type* is just a subset of A . We now define a notion of liftings for sets of types, which is instrumental in translating the transition function from states on macro-states.

Definition 5.4. The *lifting* of a type $S \in \wp A$ is defined as the following $\wp A$ -type:

$$S^\uparrow := \begin{cases} \{S\} & \text{if } S \neq \emptyset \\ \emptyset & \text{if } S = \emptyset. \end{cases}$$

This definition is extended to sets of A -types by putting $\Sigma^\uparrow := \{S^\uparrow \mid S \in \Sigma\}$.

The distinction between empty and non-empty elements of Σ is to ensure that the empty type on A is lifted to the empty type on $\wp A$. Notice that the resulting set Σ^\uparrow is either empty or contains exactly one $\wp A$ -type. This property is important for functionality, see below.

Next we define a translation on the sentences associated with the transition function of the original WMSO-automaton. Following the intuition given above, we want to work with sentences that can be made true by assigning macro-states (from $\wp A$) to finitely many nodes in the model, and ordinary states (from A) to all the other nodes. Moreover, each node should be associated with *at most one* macro-state, because of functionality. These desiderata are expressed for one-step formulas as $\wp A$ -*continuity* and $\wp A$ -*separability*, see the Definitions 4.7 and 4.15. For the language FOE_1^∞ , Theorem 4.12 and Proposition 4.17 guarantee these properties when formulas are in a certain syntactic shape. The next definition will provide formulas that conform to this particular shape.

Definition 5.5. Let $\varphi \in \text{FOE}_1^{\infty+}(A)$ be a formula of shape $\nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma)$ for some $\Pi, \Sigma \subseteq \wp A$ and $\overline{\mathbf{T}} = \{T_1, \dots, T_k\} \subseteq \wp A$. We define $\varphi^F \in \text{FOE}_1^{\infty+}(A \cup \wp A)$ as the formula

$\nabla_{\text{FOE}^\infty}^+(\bar{\mathbf{T}}^\uparrow, \Pi^\uparrow \cup \Sigma^\uparrow, \Sigma)$, that means,

$$\begin{aligned} \varphi^F := & \exists \bar{x}. \left(\text{diff}(\bar{x}) \wedge \bigwedge_{0 \leq i \leq n} \tau_{T_i}^+(x_i) \wedge \forall z. (\text{diff}(\bar{x}, z) \rightarrow \bigvee_{S \in \Pi^\uparrow \cup \Sigma^\uparrow \cup \Sigma} \tau_S^+(z)) \right) \\ & \wedge \bigwedge_{P \in \Sigma} \exists^\infty y. \tau_P^+(y) \wedge \forall^\infty y. \bigvee_{P \in \Sigma} \tau_P^+(y) \end{aligned} \quad (27)$$

We combine the previous definitions to form the transition function for macro-states.

Definition 5.6. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be a WMSO-automaton. Fix $c \in C$ and $Q \in \wp A$. By Theorem 4.12, for some $\Pi, \Sigma \subseteq \wp A$ and $T_i \subseteq A$, there is a sentence $\Psi_{Q,c} \in \text{FOE}_1^+(A)$ in the basic form $\bigvee \nabla_{\text{FOE}^\infty}^+(\bar{\mathbf{T}}, \Pi, \Sigma)$ such that $\bigwedge_{a \in Q} \Delta(a, c) \equiv \Psi_{Q,c}$. By definition $\Psi_{Q,c}$ is of the form $\bigvee_i \varphi_i$, with each φ_i of shape $\nabla_{\text{FOE}^\infty}^+(\bar{\mathbf{T}}, \Pi, \Sigma)$. We put $\Delta^\sharp(Q, c) := \bigvee_i \varphi_i^F$, where the translation $(-)^F$ is given as in Definition 5.5. Observe that $\Delta^\sharp(Q, c)$ is of type $\text{FOE}_1^+(A \cup \wp A)$.

We have now all the ingredients to define our two-sorted automaton.

Definition 5.7. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be a WMSO-automaton. We define the *finitary construct over \mathbb{A}* as the automaton $\mathbb{A}^F = \langle A^F, \Delta^F, \Omega^F, a_I^F \rangle$ given by

$$\begin{aligned} A^F &:= A \cup \wp A & \Omega^F(a) &:= \Omega(a) & \Delta^F(a, c) &:= \Delta(a, c) \\ a_I^F &:= \{a_I\} & \Omega^F(R) &:= 1 & \Delta^F(Q, c) &:= \Delta^\sharp(Q, c) \vee \bigwedge_{a \in Q} \Delta(a, c). \end{aligned}$$

Remark 5.8. In the standard powerset construction of non-deterministic parity automata ([Walukiewicz 2002], see also [Venema 2012; Arnold and Niwiński 2001]) macro-states are required to be *relations* rather than sets in order to determine whether a run through macro-states is accepting. This is not needed in our construction: macro-states will never be visited infinitely often in accepting runs, thus they may simply be assigned the priority 1.

The idea behind this definition is that \mathbb{A}^F is enforced to process only a finite portion of any accepted tree while in the non-deterministic mode. This is encoded in game-theoretic terms through the notion of functional and finitary strategy.

Definition 5.9. Given a WMSO-automaton $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ and transition system \mathbb{T} , a strategy f for \exists in $\mathcal{A}(\mathbb{A}, \mathbb{T})$ is *functional in $B \subseteq A$* (or simply functional, if $B = A$) if for each node s in \mathbb{T} there is at most one $b \in B$ such that (b, s) is a reachable position in an f -guided match. Also f is *finitary in B* if there are only finitely many nodes s in \mathbb{T} for which a position (b, s) with $b \in B$ is reachable in an f -guided match.

The next proposition establishes the desired properties of the finitary construct.

THEOREM 5.10 (SIMULATION THEOREM FOR WMSO-AUTOMATA). *Let \mathbb{A} be a WMSO-automaton and \mathbb{A}^F its finitary construct.*

- (1) \mathbb{A}^F is a WMSO-automaton.
- (2) For any tree model \mathbb{T} , if (a_I^F, s_I) is a winning position for \exists in $\mathcal{A}(\mathbb{A}^F, \mathbb{T})$, then she has a winning strategy that is both functional and finitary in $\wp A$.
- (3) $\mathbb{A} \equiv \mathbb{A}^F$.

PROOF.

- (1) Observe that any cluster of \mathbb{A}^F involves states of exactly one sort, either A or $\wp A$. For clusters on sort A , weakness and continuity of \mathbb{A}^F follow by the same properties of \mathbb{A} . For clusters on sort $\wp A$, weakness follows by observing that all macro-states

- in \mathbb{A}^F have the same priority. Concerning continuity, by definition of Δ^F any macro-state can only appear inside a formula of the form $\varphi^F = \nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}^\uparrow, \Pi^\uparrow \cup \Sigma^\uparrow, \Sigma)$ as in (27). Because $\wp A \cap \bigcup \Sigma = \emptyset$, by Theorem 4.13 φ^F is continuous in each $Q \in \wp A$.
- (2) Let f be a (positional) winning strategy for \exists in $\mathcal{A}(\mathbb{A}^F, \mathbb{T})@(\mathbf{a}_I^F, s_I)$. We define a strategy f' for \exists in the same game as follows:
- (a) On basic positions of the form $(a, s) \in A \times T$, let $V : A \rightarrow \wp R[s]$ be the valuation suggested by f . We let the valuation suggested by f' be the restriction V' of V to A . Observe that, as no predicate from $A^F \setminus A = \wp A$ occurs in $\Delta^F(a, \kappa(s)) = \Delta(a, \kappa(s))$, then V' also makes that sentence true in $R[s]$.
 - (b) For winning positions of the form $(R, s) \in \wp A \times T$, let $V_{R,s} : (\wp A \cup A) \rightarrow \wp R[s]$ be the valuation suggested by f . As f is winning, $\Delta^F(R, \kappa(s))$ is true in the model $V_{R,s}$. If this is because the disjunct $\bigwedge_{a \in R} \Delta(a, \kappa(s))$ is made true, then we can let f' suggest the restriction to A of $V_{R,s}$, for the same reason as in (a). Otherwise, the disjunct $\Delta^\sharp(R, \kappa(s)) = \bigvee_i \varphi_i^F$ is made true. This means that, for some i , $(R[s], V_{R,s}) \models \varphi_i^F$. Now, by construction of φ_i^F as in (27), we have $\wp A \cap \bigcup \Sigma = \emptyset$. By Theorem 4.13, this implies that φ_i^F is continuous in $\wp A$. Thus we have a restriction $V'_{R,s}$ of $V_{R,s}$ that verifies φ_i^F and assigns only finitely many nodes to predicates from $\wp A$. Moreover, by construction of φ_i^F , for each $S \in \{T_1^\uparrow, \dots, T_k^\uparrow\} \cup \Pi^\uparrow \cup \Sigma^\uparrow$, S contains at most one element from $\wp A$. Thus, by Proposition 4.17, φ_i^F is $\wp A$ -separable. But then we may find a separating valuation $V''_{R,s} \leq_{\wp A} V'_{R,s}$ such that $V''_{R,s}$ verifies φ_i^F . Separation means that $V''_{R,s}$ associates with each node at most one predicate from $\wp A$, and the fact that $V''_{R,s} \leq_{\wp A} V'_{R,s}$, combined with the $\wp A$ -continuity of $V'_{R,s}$ ensures $\wp A$ -continuity of $V''_{R,s}$. In this case we let f' suggest $V''_{R,s}$ at position (R, s) .
- The strategy f' defined as above is immediately seen to be surviving for \exists . It is also winning, since at every basic winning position for \exists , the set of possible next basic positions offered by f' is a subset of those offered by f . By this observation it also follows that any f' -guided match visits basic positions of the form $(R, s) \in \wp A \times C$ only finitely many times, as those have odd parity. By definition, the valuation suggested by f' only assigns finitely many nodes to predicates in $\wp A$ from positions of that shape, and no nodes from other positions. It follows that f' is finitary in $\wp A$. Functionality in $\wp A$ also follows immediately by definition of f' .
- (3) For the direction from left to right, it is immediate by definition of \mathbb{A}^F that a winning strategy for \exists in $\mathcal{G} = \mathcal{A}(\mathbb{A}, \mathbb{T})@(\mathbf{a}_I, s_I)$ is also winning for \exists in $\mathcal{G}^F = \mathcal{A}(\mathbb{A}^F, \mathbb{T})@(\mathbf{a}_I^F, s_I)$.

For the direction from right to left, let f be a winning strategy for \exists in \mathcal{G}^F . The idea is to define a strategy f' for \exists in stages, while playing a match π' in \mathcal{G} . In parallel to π' , a shadow match π in \mathcal{G}^F is maintained, where \exists plays according to the strategy f . For each round z_i , we want to keep the following relation between the two matches:

Either	
(1) positions of the form $(Q, s) \in \wp A \times T$ and $(a, s) \in A \times T$ occur respectively in π and π' , with $a \in Q$,	(†)
or	
(2) the same position of the form $(a, s) \in A \times T$ occurs in both matches.	

The key observation is that, because f is winning, a basic position of the form $(Q, s) \in \wp A \times T$ can occur only for finitely many initial rounds z_0, \dots, z_n that are played in π , whereas for all successive rounds z_n, z_{n+1}, \dots only basic positions of the

form $(a, s) \in A \times T$ are encountered. Indeed, if this was not the case then either \exists would get stuck or the highest priority occurring infinitely often would be odd, since states from $\wp A$ all have priority 1.

It follows that enforcing a relation between the two matches as in (\ddagger) suffices to prove that the defined strategy f' is winning for \exists in π' . For this purpose, first observe that $(\ddagger).1$ holds at the initial round, where the positions visited in π' and π are respectively $(a_I, s_I) \in A \times T$ and $(\{a_I\}, s_I) \in A^F \times T$. Inductively, consider any round z_i that is played in π' and π , respectively with basic positions $(a, s) \in A \times T$ and $(q, s) \in A^F \times T$. To define the suggestion of f' in π' , we distinguish two cases.

- First suppose that (q, s) is of the form $(Q, s) \in \wp A \times T$. By (\ddagger) we can assume that a is in Q . Let $V_{Q,s} : A^F \rightarrow \wp(R[s])$ be the valuation suggested by f , verifying the sentence $\Delta^F(Q, \kappa(s))$. We distinguish two further cases, depending on which disjunct of $\Delta^F(Q, \kappa(s))$ is made true by $V_{Q,s}$.
 - (i) If $(R[s], V_{Q,s}) \models \bigwedge_{b \in Q} \Delta(b, \kappa(s))$, then we let \exists pick the restriction to A of the valuation $V_{Q,s}$.
 - (ii) If $(R[s], V_{Q,s}) \models \Delta^\#(Q, \kappa(s))$, we let \exists pick a valuation $V_{a,s} : A \rightarrow \wp(R[s])$ defined by putting, for each $b \in A$:

$$V_{a,s}(b) := \bigcup_{b \in Q'} \{t \in R[s] \mid t \in V_{Q,s}(Q')\} \cup \{t \in R[s] \mid t \in V_{Q,s}(b)\}.$$

It can be readily checked that the suggested move is legitimate for \exists in π , i.e. it makes $\Delta(a, \kappa(s))$ true in $R[s]$.

For case (ii), observe that the nodes assigned to b by $V_{Q,s}$ have to be assigned to b also by $V_{a,s}$, as they may be necessary to fulfill the condition, expressed with \exists^∞ and \forall^∞ in $\Delta^\#$, that infinitely many nodes witness (or that finitely many nodes do not witness) some type.

We now show that (\ddagger) holds at round z_{i+1} . If (i) is the case, any next position $(b, t) \in A \times T$ picked by player \forall in π' is also available for \forall in π , and we end up in case $(\ddagger.2)$. Suppose instead that (ii) is the case. Given a move $(b, t) \in A \times T$ by \forall , by definition of $V_{a,s}$ there are two possibilities. First, (b, t) is also an available choice for \forall in π , and we end up in case $(\ddagger.2)$ as before. Otherwise, there is some $Q' \in \wp A$ such that b is in Q' and \forall can choose (Q', t) in the shadow match π . By letting π advance at round z_{i+1} with such a move, we are able to maintain $(\ddagger.1)$ also in z_{i+1} .

- In the remaining case, inductively we are given the same basic position $(a, s) \in A \times T$ both in π and in π' . The valuation V suggested by f in π verifies $\Delta^F(a, \kappa(s)) = \Delta(a, \kappa(s))$, thus we can let the restriction of V to A be the valuation chosen by \exists in the match π' . It is immediate that any next move of \forall in π' can be mirrored by the same move in π , meaning that we are able to maintain the same position –whence the relation $(\ddagger.1)$ – also in the next round.

In both cases, the suggestion of strategy f' was a legitimate move for \exists maintaining the relation (\ddagger) between the two matches for any next round z_{i+1} . It follows that f' is a winning strategy for \exists in \mathcal{G} .

□

5.2. From formulas to automata

In this subsection we conclude the proof of Theorem 5.2. We first focus on the case of projection with respect to finite sets, which exploits our simulation result, Theorem 5.10. The definition of the projection construction is formulated more generally

for parity automata, as it will be later applied to classes other than $Aut_{wc}(FOE_1^\infty)$. It clearly preserves the weakness and continuity conditions.

Definition 5.11. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be a parity automaton on alphabet $\wp(P \cup \{p\})$. We define the automaton $\exists p.\mathbb{A} = \langle A, \Delta^\exists, \Omega, a_I \rangle$ on alphabet $\wp P$ by putting

$$\Delta^\exists(a, c) := \Delta(a, c) \quad \Delta^\exists(Q, c) := \Delta(Q, c) \vee \Delta(Q, c \cup \{p\}).$$

The automaton $\exists p.\mathbb{A}$ is called the *finitary projection construct* of \mathbb{A} over p .

LEMMA 5.12. Let \mathbb{A} be a WMSO-automaton on alphabet $\wp(P \cup \{p\})$. Then \mathbb{A}^F is a WMSO-automaton on alphabet $\wp P$ which satisfies

$$\text{TMod}(\exists p.\mathbb{A}^F) \equiv \exists p.\text{TMod}(\mathbb{A}).$$

PROOF. Unraveling definitions, we need to show that for any tree $\mathbb{T} = \langle T, R, \kappa: P \rightarrow \wp T, s_I \rangle$:

$\exists p.\mathbb{A}^F$ accepts \mathbb{T} iff there is a finite p -variant \mathbb{T}' of \mathbb{T} such that \mathbb{A} accepts \mathbb{T}' .

For the direction from left to right, by the equivalence between \mathbb{A} and \mathbb{A}^F it suffices to show that if $\exists p.\mathbb{A}^F$ accepts \mathbb{T} then there is a finite p -variant \mathbb{T}' of \mathbb{T} such that \mathbb{A}^F accepts \mathbb{T}' . First, we first observe that the properties stated by Theorem 5.10, which hold for \mathbb{A}^F by assumption, by construction hold for $\exists p.\mathbb{A}^F$ as well. Thus we can assume that the given winning strategy f for \exists in $\mathcal{G}_\exists = \mathcal{A}(\exists p.\mathbb{A}^F, \mathbb{T}) @ (a_I^F, s_I)$ is functional and finitary in $\wp A$. Functionality allows us to associate with each node s either none or a unique state $Q_s \in \wp A$ such that (Q_s, s) is winning for \exists . We now want to isolate the nodes that f treats “as if they were labeled with p ”. For this purpose, let V_s be the valuation suggested by f from a position $(Q_s, s) \in \wp A \times T$. As f is winning, V_s makes $\Delta^\exists(Q, \kappa(s))$ true in $R[s]$. We define a p -variant $\mathbb{T}' = \langle T, R, \kappa': P \cup \{p\} \rightarrow \wp T, s_I \rangle$ of \mathbb{T} by defining $\kappa' := \kappa[p \mapsto X_p]$, that is, by colouring with p all nodes in the following set:

$$X_p := \{s \in T \mid (R[s], V_s) \models \Delta^F(Q_s, \kappa(s) \cup \{p\})\}. \quad (28)$$

The fact that f is finitary in $\wp A$ guarantees that X_p is finite, whence \mathbb{T}' is a finite p -variant. It remains to show that \mathbb{A}^F accepts \mathbb{T}' : we claim that f itself is winning for \exists in $\mathcal{G} = (\mathbb{A}^F, \mathbb{T}') @ (a_I, s_I)$. In order to see that, let us construct in stages an f -guided match π of \mathcal{G} and an f -guided shadow match $\tilde{\pi}$ of \mathcal{G}_\exists . The inductive hypothesis we want to bring from one round to the next is that the same basic position occurs in both matches, as this suffices to prove that f is winning for \exists in \mathcal{G} .

First we consider the case of a basic position $(Q, s) \in A^F \times T$ where $Q \in \wp A$. By assumption f provides a valuation V_s that makes $\Delta^\exists(Q, \kappa(s))$ true in $R[s]$. Thus V_s verifies either $\Delta^F(Q, \kappa(s))$ or $\Delta^F(Q, \kappa(s) \cup \{p\})$. Now, the match π^F is played on the p -variant \mathbb{T}' , where the labeling $\kappa'(s)$ is decided by the membership of s to X_p . According to (28), if V_s verifies $\Delta^F(Q, \kappa(s) \cup \{p\})$ then s is in X_p , meaning that it is labeled with p in \mathbb{T}' , i.e. $\kappa'(s) = \kappa(s) \cup \{p\}$. Therefore V_s also verifies $\Delta^F(Q, \kappa'(s))$ and it is a legitimate move for \exists in match π^F . In the remaining case, V_s verifies $\Delta^F(Q, \kappa(s))$ but falsifies $\Delta^F(Q, \kappa(s) \cup \{p\})$, implying by definition that s is not in X_p . This means that s is not labeled with p in \mathbb{T}' , i.e. $\kappa'(s) = \kappa(s)$. Thus again V_s verifies $\Delta^F(Q, \kappa'(s))$ and it is a legitimate move for \exists in match π^F .

It remains to consider the case of a basic position $(a, s) \in A^F \times T$ with $a \in A$ a state. By definition $\Delta^\exists(a, \kappa(s))$ is just $\Delta^F(a, \kappa(s))$. As (a, s) is winning, we can assume that no position (Q, s) with Q a macro-state is winning according to the same f , as making Δ^\exists -sentences true never forces \exists to mark a node both with a state and a macro-state. Therefore, s is not in X_p either, meaning that it is not labeled with p in the p -variant \mathbb{T}' and thus $\kappa'(s) = \kappa(s)$. This implies that f makes $\Delta^F(a, \kappa'(s)) = \Delta^F(a, \kappa(s))$ true in $R[s]$ and its suggestion is a legitimate move for \exists in match π^F . In order to conclude the

YV: see mail

proof, observe that for all positions that we consider the same valuation is suggested to \exists in both games: this means that any next position that is picked by player \forall in π^F is also available for \forall in the shadow match $\tilde{\pi}$.

We now show the direction from right to left of the statement. Let \mathbb{T}' be a finite p -variant of \mathbb{T} , with labeling function κ' , and g a winning strategy for \exists in $\mathcal{G} = \mathcal{A}(\mathbb{A}, \mathbb{T}') @ (a_I, s_I)$. Our goal is to define a strategy g' for \exists in \mathcal{G}_{\exists} . As usual, g' will be constructed in stages, while playing a match π' in \mathcal{G}_{\exists} . In parallel to π' , a *bundle* \mathcal{B} of g -guided shadow matches in \mathcal{G} is maintained, with the following condition enforced for each round z_i :

- (1) If the current basic position in π' is of the form $(Q, s) \in \wp A \times T$, then for each $a \in Q$ there is an g -guided (partial) shadow match π_a at basic position $(a, s) \in A \times T$ in the current bundle \mathcal{B}_i . Also, either \mathbb{T}'_s is not p -free (i.e., it does contain a node s' with $p \in \kappa'(s')$) or s has some sibling t such that \mathbb{T}'_t is not p -free.
 - (2) Otherwise, the current basic position in π' is of the form $(a, s) \in A \times T$ and \mathbb{T}'_s is p -free. Also, the bundle \mathcal{B}_i only consists of a single g -guided match π_a whose current basic position is also (a, s) .
- (‡)

We recall the idea behind (‡). Point (‡.1) describes the part of match π' where it is still possible to encounter nodes which are labeled with p in \mathbb{T}' . As Δ^{\exists} only takes the letter p into account when defined on macro-states in $\wp A$, we want π' to visit only positions of the form $(Q, s) \in \wp A \times T$ in that situation. Anytime we visit such a position (Q, s) in π' , the role of the bundle is to provide one g -guided shadow match at position (a, s) for each $a \in Q$. Then g' is defined in terms of what g suggests from those positions.

Point (‡.2) describes how we want the match π' to be played on a p -free subtree: as any node that one might encounter has the same label in \mathbb{T} and \mathbb{T}' , it is safe to let $\exists_F p. \mathbb{A}^F$ behave as \mathbb{A} in such situation. Provided that the two matches visit the same basic positions, of the form $(a, s) \in A \times T$, we can let g' just copy g .

The key observation is that, as \mathbb{T}' is a *finite* p -variant of \mathbb{T} , nodes labeled with p are reachable only for finitely many rounds of π' . This means that, provided that (‡) hold at each round, (‡.1) will describe an initial segment of π' , whereas (‡.2) will describe the remaining part. Thus our proof that g' is a winning strategy for \exists in \mathcal{G}_{\exists} is concluded by showing that (‡) holds for each stage of construction of π' and \mathcal{B} .

For this purpose, we initialize π' from position $(a_I^\sharp, s) \in \wp A \times T$ and the bundle \mathcal{B} as $\mathcal{B}_0 = \{\pi_{a_I}\}$, with π_{a_I} the partial g -guided match consisting only of the position $(a_I, s) \in A \times T$. The situation described by (‡.1) holds at the initial stage of the construction. Inductively, suppose that at round z_i we are given a position $(q, s) \in A^F \times T$ in π^F and a bundle \mathcal{B}_i as in (‡). To show that (‡) can be maintained at round z_{i+1} , we distinguish two cases, corresponding respectively to situation (‡.1) and (‡.2) holding at round z_i .

- (A) If (q, s) is of the form $(Q, s) \in \wp A \times T$, by inductive hypothesis we are given with g -guided shadow matches $\{\pi_a\}_{a \in Q}$ in \mathcal{B}_i . For each match π_a in the bundle, we are provided with a valuation $V_{a,s} : A \rightarrow \wp(R[s])$ making $\Delta(a, \kappa'(s))$ true. Then we further distinguish the following two cases.

- (i) Suppose first that \mathbb{T}'_s is not p -free. We let the suggestion $V': A^F \rightarrow \wp(R[s])$ of g' from position (Q, s) be defined as follows:

$$V'(q') := \begin{cases} \bigcap_{\substack{(a,b) \in q', \\ a \in Q}} \{t \in R[s] \mid t \in V_{a,s}(b)\} & q' \in \wp A \\ \bigcup_{a \in Q} \{t \in R[s] \mid t \in V_{a,s}(q') \text{ and } \mathbb{T}'.t \text{ is } p\text{-free}\} & q' \in A. \end{cases}$$

The definition of V' on $q' \in \wp A$ is standard (cf. [Zanasi 2012, Prop. 2.21]) and guarantees a correspondence between the states assigned by the valuations $\{V_{a,s}\}_{a \in Q}$ and the macro-states assigned by V' . The definition of V' on $q' \in A$ aims at fulfilling the conditions, expressed via \exists^∞ and \forall^∞ , on the number of nodes in $R[s]$ witnessing (or not) some A -types. Those conditions are the ones that $\Delta^\sharp(Q, \kappa'(s))$ –and thus also $\Delta^F(Q, \kappa'(s))$ – “inherits” by $\bigwedge_{a \in R} \Delta(a, \kappa'(s))$, by definition of Δ^\sharp . Notice that we restrict $V'(q')$ to the nodes $t \in V_{a,s}(q')$ such that $\mathbb{T}'.t$ is p -free. As \mathbb{T}' is a *finite* p -variant, only *finitely many* nodes in $V_{a,s}(q')$ will not have this property. Therefore their exclusion, which is crucial for maintaining condition (\ddagger) (cf. case (a) below), does not influence the fulfilling of the cardinality conditions expressed via \exists^∞ and \forall^∞ in $\Delta^\sharp(Q, \kappa'(s))$.

On the base of these observations, one can check that V' makes $\Delta^\sharp(Q, \kappa'(s))$ –and thus also $\Delta^F(Q, \kappa'(s))$ –true in $R[s]$. In fact, to be a legitimate move for \exists in π' , V' should make $\Delta^\exists(Q, \kappa(s))$ true: this is the case, for $\Delta^F(Q, \kappa'(s))$ is either equal to $\Delta^F(Q, \kappa(s))$, if $p \notin \kappa'(s)$, or to $\Delta^F(Q, \kappa(s) \cup \{p\})$ otherwise. In order to check that we can maintain (\ddagger) , let $(q', t) \in A^F \times T$ be any next position picked by \forall in π' at round z_{i+1} . As before, we distinguish two cases:

- (a) If q' is in A , then, by definition of V' , \forall can choose (q', t) in some shadow match π_a in the bundle \mathcal{B}_i . We dismiss the bundle –i.e. make it a singleton– and bring only π_a to the next round in the same position (q', t) . Observe that, by definition of V' , $\mathbb{T}'.t$ is p -free and thus $(\ddagger.2)$ holds at round z_{i+1} .
 - (b) Otherwise, q' is in $\wp A$. The new bundle \mathcal{B}_{i+1} is given in terms of the bundle \mathcal{B}_i : for each $\pi_a \in \mathcal{B}_i$ with $a \in Q$, we look if for some $b \in q'$ the position (b, t) is a legitimate move for \forall at round z_{i+1} ; if so, then we bring π_a to round z_{i+1} at position (b, t) and put the resulting (partial) shadow match π_b in \mathcal{B}_{i+1} . Observe that, if \forall is able to pick such position (q', t) in π' , then by definition of V' the new bundle \mathcal{B}_{i+1} is non-empty and consists of an g -guided (partial) shadow match π_b for each $b \in q'$. In this way we are able to keep condition $(\ddagger.1)$ at round z_{i+1} .
- (ii) Let us now consider the case in which \mathbb{T}'_s is p -free. We let g' suggest the valuation V' that assigns to each node $t \in R[s]$ all states in $\bigcup_{a \in Q} \{b \in A \mid t \in V_{a,s}(b)\}$. It can be checked that V' makes $\bigwedge_{a \in Q} \Delta(a, \kappa'(s))$ – and then also $\Delta^F(Q, \kappa'(s))$ – true in $R[s]$. As $p \notin \kappa(s) = \kappa'(s)$, it follows that V' also makes $\Delta^\exists(Q, \kappa(s))$ true, whence it is a legitimate choice for \exists in π' . Any next basic position picked by \forall in π' is of the form $(b, t) \in A \times T$, and thus condition $(\ddagger.2)$ holds at round z_{i+1} as shown in (i.a).
- (B) In the remaining case, (q, s) is of the form $(a, s) \in A \times T$ and by inductive hypothesis we are given with a bundle \mathcal{B}_i consisting of a single f -guided (partial) shadow match π_a at the same position (a, s) . Let $V_{a,s}$ be the suggestion of \exists from position (a, s) in π_a . Since by assumption s is p -free, we have that $\kappa'(s) = \kappa(s)$, meaning that $\Delta^\exists(a, \kappa(s))$ is just $\Delta(a, \kappa(s)) = \Delta(a, \kappa'(s))$. Thus the restriction V' of V to A makes $\Delta(a, \kappa'(t))$ true and we let it be the choice for \exists in π . It follows that any next move made by \forall in π can be mirrored by \forall in the shadow match π_a .

□

5.2.1. Closure under Boolean operations. Here we show that the collection of $Aut(WMSO)$ -recognizable classes of tree models is closed under the Boolean operations. For union, we use the following result, leaving the straightforward proof as an exercise to the reader.

LEMMA 5.13. *Let \mathbb{A}_0 and \mathbb{A}_1 be WMSO-automata. Then there is a WMSO-automaton \mathbb{A} such that $TMod(\mathbb{A})$ is the union of $TMod(\mathbb{A}_0)$ and $TMod(\mathbb{A}_1)$.*

For closure under complementation we reuse the general results established in Section 4 for parity automata.

LEMMA 5.14. *Let \mathbb{A} be an WMSO-automaton. Then the automaton $\overline{\mathbb{A}}$ defined in Definition 4.19 is a WMSO-automaton recognizing the complement of $TMod(\mathbb{A})$.*

PROOF. It suffices to check that Proposition 4.20 restricts to the class $Aut_{wc}(FOE_1^\infty)$ of WMSO-automata. First, the fact that FOE_1^∞ is closed under Boolean duals (Definition 4.6) implies that it holds for the class $Aut(FOE_1^\infty)$. It then remains to check that the dual automata construction $\overline{(\cdot)}$ preserves weakness and continuity. But this is straightforward, given the self-dual nature of these properties. □

We are now finally able to conclude the direction from formulas to automata of the characterisation theorem.

PROOF OF THEOREM 5.2. The proof is by induction on φ .

- For the base case, we consider the atomic formulas $\Downarrow p$, $p \sqsubseteq q$ and $R(p, q)$.
 - The WMSO-automaton $\mathbb{A}_{\Downarrow p} = \langle A, \Delta, \Omega, a_I \rangle$ is given by putting

$$A := \{a_0, a_1\} \quad a_I := a_0 \quad \Omega(a_0) := 0 \quad \Omega(a_1) := 0$$

$$\Delta(a_0, c) := \begin{cases} \forall x. a_1(x) & \text{if } p \in c \\ \perp & \text{otherwise.} \end{cases} \quad \Delta(a_1, c) := \begin{cases} \forall x. a_1(x) & \text{if } p \notin c \\ \perp & \text{otherwise.} \end{cases}$$
 - The WMSO-automaton $\mathbb{A}_{p \sqsubseteq q} = \langle A, \Delta, \Omega, a_I \rangle$ is given by $A := \{a\}$, $a_I := a$, $\Omega(a) := 0$ and $\Delta(a, c) := \forall x a(x)$ if $p \notin c$ or $q \in c$, and $\Delta(a, c) := \perp$ otherwise.
 - The WMSO-automaton $\mathbb{A}_{R(p, q)} = \langle A, \Delta, \Omega, a_I \rangle$ is given below:

$$A := \{a_0, a_1\} \quad a_I := a_0 \quad \Omega(a_0) := 0 \quad \Omega(a_1) := 1$$

$$\Delta(a_0, c) := \begin{cases} \exists x. a_1(x) \wedge \forall y. a_0(y) & \text{if } p \in c \\ \forall x (a_0(x)) & \text{otherwise.} \end{cases} \quad \Delta(a_1, c) := \begin{cases} \top & \text{if } q \in c \\ \perp & \text{otherwise} \end{cases}$$
- For the Boolean cases, where $\varphi = \psi_1 \vee \psi_2$ or $\varphi = \neg\psi$ we refer to the Boolean closure properties that we just established in the Lemmas 5.13 and 5.14, respectively.
- The case $\varphi = \exists p. \psi$ follows by the following chain of equivalences, where \mathbb{A}_ψ is given by the inductive hypothesis and $\exists_F p. \mathbb{A}_\psi$ is constructed according to Definition 5.11:

$$\begin{aligned} \exists_F p. \mathbb{A}_\psi \text{ accepts } T & \text{ iff } \mathbb{A}_\psi \text{ accepts } T[p \mapsto X], \text{ for some } X \subseteq_\omega T & (\text{Lemma 5.12}) \\ & \text{ iff } T[p \mapsto X] \models \psi, \text{ for some } X \subseteq_\omega T & (\text{induction hyp.}) \\ & \text{ iff } T \models \exists p. \psi & (\text{semantics WMSO}) \end{aligned}$$

□

6. AUTOMATA FOR NMSO

In this section we introduce the automata that capture NMSO.

Definition 6.1. A NMSO-automaton is a weak automaton for the one-step language FOE_1 .

Analogous to the previous section, our main goal here is to construct an equivalent NMSO-automaton for every NMSO-formula.

THEOREM 6.2. *There is an effective construction transforming a NMSO-formula φ into a NMSO-automaton \mathbb{A}_φ that is equivalent to φ on the class of trees.*

The proof for Theorem 6.2 will closely follow the steps for proving the analogous result for WMSO (Theorem 5.2). Again, the crux of the matter is to show that the collection of classes of tree models that are recognisable by some NMSO-automaton, is closed under the relevant notion of projection. Where this was finitary projection for WMSO (Def. 5.3), the notion mimicking NMSO-quantification is *noetherian* projection.

Definition 6.3. Given a set P of proposition letters, $p \notin P$ and a class C of $P \cup \{p\}$ -labeled trees, we define the *noetherian projection* of C over p as the language of P -labeled trees given as

$$\exists_{Np}.C := \{\mathbb{T} \mid \text{there is a noetherian } p\text{-variant } \mathbb{T}' \text{ of } \mathbb{T} \text{ with } \mathbb{T}' \in C\}.$$

A collection of classes of tree models is *closed under noetherian projection over p* if it contains the class $\exists_{Np}.C$ whenever it contains the class C itself.

6.1. Simulation theorem for NMSO-automata

Just as for WMSO-automata, also for NMSO-automata the projection construction will rely on a simulation theorem, constructing a two-sorted automaton \mathbb{A}^N consisting of a copy of the original automaton, based on states A , and a variation of its powerset construction, based on macro-states $\wp A$. For any accepted \mathbb{T} , we want any match π of $\mathcal{A}(\mathbb{A}^N, \mathbb{T})$ to split in two parts:

(*Non-deterministic mode*). for finitely many rounds π is played on macro-states, i.e. positions are of the form $\wp A \times T$. The strategy of player \exists is functional in $\wp A$, i.e. it assigns *at most one macro-state* to each node.

(*Alternating mode*). At a certain round, π abandons macro-states and turns into a match of the game $\mathcal{A}(\mathbb{A}, \mathbb{T})$, i.e. all next positions are from $A \times T$ (and are played according to a non-necessarily functional strategy).

The only difference with the two-sorted construction for WMSO-automata is that, in the non-deterministic mode, the cardinality of nodes to which \exists 's strategy assigns macro-states is irrelevant. Indeed, NMSO's finiteness is only on the vertical dimension: assigning an odd priority to macro-states will suffice to guarantee that the non-deterministic mode processes just a well-founded portion of any accepted tree.

We now proceed in steps towards the construction of \mathbb{A}^N . First, the following lifting from states to macro-states parallels Definition 5.5, but for the one-step language FOE_1 proper of NMSO-automata. It is based on the basic form for FOE_1 -formulas, see Definition 4.11.

Definition 6.4. Let $\varphi \in \text{FOE}_1^+(A)$ be of shape $\nabla_{\text{FOE}}^+(\overline{\mathbb{T}}, \Pi)$ for some $\Pi \subseteq \wp A$ and $\overline{\mathbb{T}} = \{T_1, \dots, T_k\} \subseteq \wp A$. We define φ^N as $\nabla_{\text{FOE}}^+(\overline{\mathbb{T}}^\uparrow, \Pi^\uparrow) \in \text{FOE}_1^+(\wp A)$, that means,

$$\varphi^N := \exists \overline{x}. (\text{diff}(\overline{x}) \wedge \bigwedge_{0 \leq i \leq n} \tau_{T_i^\uparrow}^+(x_i) \wedge \forall z. (\text{diff}(\overline{x}, z) \rightarrow \bigvee_{S \in \Pi^\uparrow} \tau_S^+(z))) \quad (29)$$

It is instructive to compare (29) with its WMSO-counterpart (27): the difference is that, because the quantifiers \exists^∞ and \forall^∞ are missing, the sentence does not impose any cardinality requirement, but only enforces $\wp A$ -separability — cf. Section 4.1.

LEMMA 6.5. *Let $\varphi \in \text{FOE}_1^+(A)$ and $\varphi^N \in \text{FOE}_1^+(\wp A)$ be as in Definition 6.4. Then φ^N is separating in $\wp A$.*

PROOF. Each element of $\overline{\mathbb{T}}^\uparrow$ and Π^\uparrow is by definition either the empty set or a singleton $\{Q\}$ for some $Q \in \wp A$. Then the statement follows from Proposition 4.17. \square

We are now ready to define the transition function for macro-states. The following adapts Definition 5.6 to the one-step language FOE_1 of NMSO-automata, and its normal form result, Theorem 4.12.

Definition 6.6. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be a NMSO-automaton. Fix any $c \in C$ and $Q \in \wp A$. By Theorem 4.12 there is a sentence $\Psi_{Q,c} \in \text{FOE}_1^+(A)$ in the basic form $\bigvee \nabla_{\text{FOE}}(\overline{\mathbb{T}}, \Pi)$, for some $\Pi \subseteq \wp A$ and $T_i \subseteq A$, such that $\bigwedge_{a \in Q} \Delta(a, c) \equiv \Psi_{Q,c}$. By definition, $\Psi_{Q,c} = \bigvee_n \varphi_n$, with each φ_n of shape $\nabla_{\text{FOE}}(\overline{\mathbb{T}}, \Pi)$. We put $\Delta^b(Q, c) := \bigvee_n \varphi_n^N \in \text{FOE}_1^+(\wp A)$, where the translation $(\cdot)^N$ is as in Definition 6.4.

We now have all the ingredients for the two-sorted construction over NMSO-automata.

Definition 6.7. Let $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ be a NMSO-automaton. We define the *noetherian construct* over \mathbb{A} as the automaton $\mathbb{A}^N = \langle A^N, \Delta^N, \Omega^N, a_I^N \rangle$ given by

$$\begin{aligned} A^N &:= A \cup \wp A & \Omega^N(a) &:= \Omega(a) & \Delta^N(a, c) &:= \Delta(a, c) \\ a_I^N &:= \{a_I\} & \Omega^N(R) &:= 1 & \Delta^N(Q, c) &:= \Delta^b(Q, c) \vee \bigwedge_{a \in Q} \Delta(a, c). \end{aligned}$$

The construction is the same as the one for WMSO-automata (Definition 5.7) but for the definition of the transition function for macro-states, which is now free of any cardinality requirement.

Definition 6.8. We say that a strategy f in an acceptance game $\mathcal{A}(\mathbb{A}, \mathbb{T})$ is *noetherian* in $B \subseteq A$ when in any f -guided match there can be only finitely many rounds played at a position of shape (q, s) with $q \in B$.

THEOREM 6.9 (SIMULATION THEOREM FOR NMSO-AUTOMATA). *Let \mathbb{A} be an NMSO-automaton and \mathbb{A}^N its noetherian construct.*

- (1) \mathbb{A}^N is an NMSO-automaton.
- (2) For any \mathbb{T} , if \exists has a winning strategy in $\mathcal{A}(\mathbb{A}^N, \mathbb{T})$ from position (a_I^N, s_I) then she has one that is functional in $\wp A$ and noetherian in $\wp A$.
- (3) $\mathbb{A} \equiv \mathbb{A}^N$.

PROOF. The proof follows the same steps as the one of Proposition 5.10, minus all the concerns about continuity of the constructed automaton and any associated winning strategy f being finitary. One still has to show that f is noetherian in $\wp A$ (“vertically finitary”), but this is enforced by macro-states having an odd parity: visiting one of them infinitely often would mean \exists ’s loss. \square

Remark 6.10. As mentioned, the class $\text{Aut}(\text{FOE}_1)$ of automata characterising SMSO [Janin and Walukiewicz 1996] also enjoys a simulation theorem [Walukiewicz 1996], turning any automaton into an equivalent non-deterministic one. Given that the class $\text{Aut}_w(\text{FOE}_1)$ only differs for the weakness constraint, one may wonder if the simulation result for $\text{Aut}(\text{FOE}_1)$ could not actually be restricted to $\text{Aut}_w(\text{FOE}_1)$, making our two-sorted construction redundant. This is actually not the case: not only does Walukiewicz’s simulation theorem [Walukiewicz 1996] fail to preserve the weakness

constraint, but even without this failure our purposes would not be served: A fully non-deterministic automaton is instrumental in guessing a p -variant of any accepted tree, but it does not guarantee that the p -variant is also noetherian, as the two-sorted construct does.

6.2. From formulas to automata

We can now conclude one direction of the automata characterisation of NMSO.

LEMMA 6.11. *For each NMSO-automaton \mathbb{A} on alphabet $\wp(\mathcal{P} \cup \{p\})$, let \mathbb{A}^N be its noetherian construct. We have that*

$$\text{TMod}(\exists p.\mathbb{A}^N) \equiv \exists_N p.\text{TMod}(\mathbb{A}).$$

PROOF. The argument is the same as for WMSO-automata (Lemma 5.12). As in that proof, the inclusion from left to right relies on the simulation result (Theorem 6.9): $\exists p.\mathbb{A}^N$ is two-sorted and its non-deterministic mode can be used to guess a noetherian p -variant of any accepted tree. \square

PROOF OF THEOREM 6.2. As for its WMSO-counterpart Theorem 5.2, the proof is by induction on $\varphi \in \text{NMSO}$. The boolean inductive cases are handled by the NMSO-versions of Lemma 5.13 and 5.14. The projection case follows from Lemma 6.11. \square

7. FIXPOINT OPERATORS AND SECOND-ORDER QUANTIFIERS

In this section we will show how to translate some of the mu-calculi that we encountered until now into the appropriate second-order logics. Given the equivalence between automata and fixpoint logics that we established in Section 4, and the embeddings of WMSO and NMSO into, respectively, the automata classes $Aut_{wc}(FOE_1^\infty)$ and $Aut_w(FOE_1)$ that we provided in the Sections 5 and 6 for the class of tree models, the results here provide the missing link in the automata-theoretic characterizations of the monadic second order logics WMSO and NMSO:

$$\begin{aligned}\mu_C(FOE_1^\infty) &\equiv \text{WMSO} && \text{(over the class of all tree models)} \\ \mu_N(FOE_1) &\equiv \text{NMSO} && \text{(over the class of all tree models)}.\end{aligned}$$

7.1. Translating μ -calculi into second-order logics

More specifically, our aim in this Section is to prove the following result.

THEOREM 7.1.

- (1) *There is an effective translation $(\cdot)^* : \mu_N FOE_1 \rightarrow \text{NMSO}$ such that $\varphi \equiv \varphi^*$ for every $\varphi \in \mu_N FOE_1$; that is:*

$$\mu_N FOE_1 \leq \text{NMSO}.$$

- (2) *There is an effective translation $(\cdot)^* : \mu_C FOE_1^\infty \rightarrow \text{WMSO}$ such that $\varphi \equiv \varphi^*$ for every $\varphi \in \mu_C FOE_1^\infty$; that is:*

$$\mu_C FOE_1^\infty \leq \text{WMSO}.$$

Two immediate observations on this Theorem are in order. First, note that we use the same notation $(\cdot)^*$ for both translations; this should not cause any confusion since the maps agree on formulas belonging to their common domain. Consequently, in the remainder we will speak of a single translation $(\cdot)^*$. Second, as the target language of the translation $(\cdot)^*$ we will take the *two-sorted* version of second-order logic, as discussed in section 3.1, and thus we will need Proposition 3.5 to obtain the result as formulated in Theorem 7.1, that is, for the one-sorted versions of MSO. We reserve a fixed individual variable v for this target language, i.e., every formula of the form φ^* will have this v as its unique free variable; the equivalence $\varphi \equiv \varphi^*$ is to be understood accordingly.

The translation $(\cdot)^*$ will be defined by a straightforward induction on the complexity of fixpoint formulas. The two clauses of this definition that deserve some special attention are the ones related to the fixpoint operators and the modalities.

Fixpoint operators. It is important to realise that our clause for the fixpoint operators *differs* from the one used in the standard inductive translation $(\cdot)^s$ of μML into standard MSO, where we would inductively translate $(\mu p.\varphi)^*$ as

$$\forall p (\forall w (\varphi^*[w/v] \rightarrow p(w)) \rightarrow p(v)), \quad (30)$$

which states that v belongs to any prefixpoint of φ with respect to p . To understand the problem with this translation in the current context, suppose, for instance, that we want to translate some continuous μ -calculus into WMSO. Then the formula in (30) expresses that v belongs to the intersection of all *finite* prefixpoints of φ , whereas the least fixpoint is identical to the intersection of *all* prefixpoints. As a result, (30) does not give the right translation for the formula $\mu p.\varphi$ into WMSO.

To overcome this problem, we will prove that least fixpoints in restricted calculi like $\mu_N FOE_1$, $\mu_C FOE_1^\infty$ and many others, in fact satisfy a rather special property, which enables an alternative translation. We need the following definition to formulate this property.

Definition 7.2. Let $F : \wp(S) \rightarrow \wp(S)$ be a functional; for a given $X \subseteq S$ we define the restricted map $F_{\upharpoonright_X} : \wp(S) \rightarrow \wp(S)$ by putting $F_{\upharpoonright_X}(Y) := FY \cap X$. **In case F is monotone, we will use $LFP.F$ to denote its least fixpoint.**

The observations formulated in the proposition below provide the crucial insight underlying our embedding of various alternation-free and continuous μ -calculi into, respectively, NMSO and WMSO.

PROPOSITION 7.3. *Let \mathbb{S} be an LTS, and let r be a point in \mathbb{S} .*

(1) *For any formula φ with $\mu p.\varphi \in \mu_N\text{FOE}_1$ we have*

$$r \in \llbracket \mu p.\varphi \rrbracket^{\mathbb{S}} \text{ iff there is a noetherian set } X \text{ such that } r \in LFP.(\varphi_p^{\mathbb{S}})_{\upharpoonright_X}. \quad (31)$$

(2) *For any formula φ with $\mu p.\varphi \in \mu_C\text{FOE}_1^{\infty}$ we have*

$$r \in \llbracket \mu p.\varphi \rrbracket^{\mathbb{S}} \text{ iff there is a finite set } X \text{ such that } r \in LFP.(\varphi_p^{\mathbb{S}})_{\upharpoonright_X}. \quad (32)$$

Remark 7.4. In fact, the statements in Proposition 7.3 can be generalised to the setting of a fixpoint logic μL_1 associated with an arbitrary one-step language L_1 .

The right-to-left direction of both (31) and (32) follow from the following, more general, statement, which can be proved by a routine argument.

PROPOSITION 7.5. *Let $F, G : \wp(S) \rightarrow \wp(S)$ be monotone, and assume that $F(Y) \subseteq G(Y)$, for every $Y \in \wp(S)$. Then $LFP.F \subseteq LFP.G$.*

The left-to-right direction of (31) and (32) will be proved in the next two subsections. Note that in the continuous case we will in fact prove a slightly stronger result, which applies to *arbitrary* continuous functionals.

The point of Proposition 7.3 is that it naturally suggests the following translation for the least fixpoint operator, as a subtle but important variation of (30):

$$(\mu p.\varphi)^* := \exists q \left(\forall p \subseteq q. (p \in PRE((\varphi_p^{\mathbb{S}})_{\upharpoonright_q}) \rightarrow p(v)) \right), \quad (33)$$

where $p \in PRE((\varphi_p^{\mathbb{S}})_{\upharpoonright_q})$ expresses that $p \subseteq q$ is a prefixpoint of the map $(\varphi_p^{\mathbb{S}})_{\upharpoonright_q}$, that is:

$$p \in PRE((\varphi_p^{\mathbb{S}})_{\upharpoonright_q}) := \forall w \left((q(w) \wedge \varphi^*[w/v]) \rightarrow p(w) \right).$$

Modalities. Finally, before we can give the definition of the translation $(\cdot)^*$, we briefly discuss the clause involving the modalities. Here we need to understand the role of the *one-step formulas* in the translation. First an auxiliary definition.

Definition 7.6. Let $\mathbb{S} = \langle T, R, \kappa, s_I \rangle$ be a P-LTS, let A be a set of new variables, and let $V : A \rightarrow \wp(X)$ be a valuation on a subset $X \subseteq T$. The $(P \cup A)$ -LTS $\mathbb{S}^V := \langle T, R, \kappa^V, s_I \rangle$, given by defining the marking $\kappa^V : T \rightarrow \wp(P \cup A)$ where

$$\kappa^V(s) := \begin{cases} \kappa(s) & \text{if } s \notin X \\ \kappa(s) \cup \{a \in A \mid s \in V(a)\} & \text{else,} \end{cases}$$

is called the *V-expansion* of \mathbb{S} .

The following proposition states that at the one-step level, the formulas that provide the semantics of the modalities of μFOE_1 and μFOE_1^{∞} can indeed be translated into, respectively NMSO and WMSO.

PROPOSITION 7.7. *There is a translation $(\cdot)^\dagger : \text{FOE}_1^\infty(A) \rightarrow \text{WMSO}$ such that for every model \mathbb{S} and every valuation $V : A \rightarrow \wp(R[s_I])$:*

$$(R[s_I], V) \models \alpha \text{ iff } \mathbb{S}^V \models \alpha^\dagger[s_I].$$

Moreover, $(\cdot)^\dagger$ restricts to first-order logic, i.e., α^\dagger is a first-order formula if $\alpha \in \text{FOE}_1$.

PROOF. Basically, the translation $(\cdot)^\dagger$ restricts all quantifiers to the collection of successors of v . In other words, $(\cdot)^\dagger$ is the identity on basic formulas, it commutes with the propositional connectives, and for the quantifiers \exists and \exists^∞ we define:

$$\begin{aligned} (\exists x \alpha)^\dagger &:= \exists x (Rvx \wedge \alpha^\dagger) \\ (\exists^\infty x \alpha)^\dagger &:= \forall p \exists x (Rvx \wedge \neg p(x) \wedge \alpha^\dagger) \end{aligned}$$

We leave it for the reader to verify the correctness of this definition — observe that the clause for the infinity quantifier \exists^∞ is based on the equivalence between WMSO and FOE^∞ , established by Väänänen [Väänänen 1977]. \square

We are now ready to define the translation used in the main result of this section.

Definition 7.8. By an induction on the complexity of formulas we define the following translation $(\cdot)^*$ from μFOE^∞ -formulas to formulas of monadic second-order logic:

$$\begin{aligned} p^* &:= p(v) \\ (\neg \varphi)^* &:= \neg \varphi^* \\ (\varphi \vee \psi)^* &:= \varphi^* \vee \psi^* \\ (\bigcirc_\alpha(\overline{\varphi}))^* &:= \alpha^\dagger[\varphi_i^*/a_i \mid i \in I], \end{aligned}$$

where α^\dagger is as in Proposition 7.7, and $[\varphi_i^*/a_i \mid i \in I]$ is the substitution that replaces every occurrence of an atomic formula of the form $a_i(x)$ with the formula $\varphi_i^*(x)$ (i.e. the formula φ_i^* , but with the free variable v substituted by x).

Finally, the inductive clause for a formula of the form $\mu p. \varphi$ is given as in (33).

PROOF OF THEOREM 7.1. First of all, it is clear that in both cases the translation $(\cdot)^*$ lands in the correct language. For both parts of the theorem, we thence prove that $(\cdot)^*$ is truth preserving by a straightforward formula induction. E.g., for part (2) we need to show that, for an arbitrary formula $\varphi \in \mu_C \text{FOE}_1^\infty$ and an arbitrary model \mathbb{S} :

$$\mathbb{S} \Vdash \varphi \text{ iff } \mathbb{S} \models \varphi^*[s_I]. \quad (34)$$

As discussed in the main text, the two critical cases concern the inductive steps for the modalities and the least fixpoint operators. Let $L_1^+ \in \{\text{FOE}_1, \text{FOE}_1^\infty\}$. We start verifying the case of modalities. Hence, consider the formula $\bigcirc_\alpha(\varphi_1, \dots, \varphi_n)$ with $\alpha(a_1, \dots, a_n) \in L_1^+$. By induction hypothesis, $\varphi_\ell \equiv \varphi_\ell^*$, for $\ell = 1, \dots, n$. Now, let \mathbb{S} be a transition system. We have that

$$\begin{aligned} \mathbb{S} \Vdash \bigcirc_\alpha(\varphi_1, \dots, \varphi_n) &\text{ iff } (R[s_I], V_{\overline{\varphi}}) \models \alpha(a_1, \dots, a_n) && \text{(by (25))} \\ &\text{ iff } \mathbb{S}^{V_{\overline{\varphi}}} \models \alpha^\dagger[s_I] && \text{(by Prop. 7.7)} \\ &\text{ iff } \mathbb{S} \models \alpha^\dagger[\varphi_i^*/a_i \mid i \in I][s_I] && \text{(by (26), Def. 7.6 and IH)} \end{aligned}$$

The inductive step for the least fixpoint operator will be justified by Proposition 7.3. In more detail, given a formula of the form $\mu x. \psi \in \mu_Y L_1^+$, with $Y = D$ for $L_1^+ = \text{FOE}_1$,

and $Y = C$ for $L_1^+ = \text{FOE}_1^\infty$, consider the following chain of equivalences:

$$\begin{aligned}
& s_I \in \llbracket \mu p. \psi \rrbracket^S \\
& \text{iff } s_I \in LFP.(\psi_p^S)_{\upharpoonright_Q} \text{ for some } \begin{cases} \text{finite} \\ \text{noetherian} \end{cases} \text{ set } Q \quad (\text{by (31)/(32)}) \\
& \text{iff } s_I \in \bigcap \left\{ P \subseteq Q \mid P \in PRE((\psi_p^S)_{\upharpoonright_Q}) \right\} \text{ for some } \begin{cases} \text{finite} \\ \text{noetherian} \end{cases} \text{ set } Q \\
& \text{iff } S \models \exists q. (\forall p \subseteq q. (p \in PRE((\psi_p^S)_{\upharpoonright_q}) \rightarrow p(s_I))) \\
& \text{iff } S \models (\mu p. \psi)^*[s_I]. \quad (\text{IH})
\end{aligned}$$

This concludes the proof of (34). \square

7.2. Fixpoints of continuous maps

It is well-known that continuous functionals are *constructive*. That is, if we construct the least fixpoint of a continuous functional $F : \wp(S) \rightarrow \wp(S)$ using the ordinal approximation $\emptyset, F\emptyset, F^2\emptyset, \dots, F^\alpha\emptyset, \dots$, then we reach convergence after at most ω many steps, implying that $LFP.F = F^\omega\emptyset$. We will see now that this fact can be strengthened to the following observation, which is the crucial result needed in the proof of Proposition 7.3.

THEOREM 7.9. *Let $F : \wp(S) \rightarrow \wp(S)$ be a continuous functional. Then for any $s \in S$:*

$$s \in LFP.F \text{ iff } s \in LFP.F_{\upharpoonright_X}, \text{ for some finite } X \subseteq S. \quad (35)$$

PROOF. The direction from right to left of (35) is a special case of Proposition 7.5. For the opposite direction of (35) a bit more work is needed. Assume that $s \in LFP.F$; we claim that there are sets U_1, \dots, U_n , for some $n \in \omega$, such that $s \in U_n$, $U_1 \subseteq_\omega F(\emptyset)$, and $U_{i+1} \subseteq_\omega F(U_i)$, for all i with $1 \leq i < n$.

To see this, first observe that since F is continuous, we have $LFP.F = F^\omega(\emptyset) = \bigcup_{n \in \omega} F^n(\emptyset)$, and so we may take n to be the least natural number such that $s \in F^n(\emptyset)$. By a downward induction we now define sets U_n, \dots, U_1 , with $U_i \subseteq F^i(\emptyset)$ for each i . We set up the induction by putting $U_n := \{s\}$, then $U_n \subseteq F^n(\emptyset)$ by our assumption on n . For $i < n$, we define U_i as follows. Using the inductive fact that $U_{i+1} \subseteq_\omega F^{i+1}(\emptyset) = F(F^i(\emptyset))$, it follows by continuity of F that for each $u \in U_{i+1}$ there is a set $V_u \subseteq_\omega F^i(\emptyset)$ such that $u \in F(V_u)$. We then define $U_i := \bigcup \{V_u \mid u \in U_{i+1}\}$, so that clearly $U_{i+1} \subseteq_\omega F(U_i)$ and $U_i \subseteq_\omega F^i(\emptyset)$. Continuing like this, ultimately we arrive at stage $i = 1$ where we find $U_1 \subseteq F(\emptyset)$ as required.

Finally, given the sequence U_n, \dots, U_1 , we define

$$X := \bigcup_{0 < i \leq n} U_i.$$

It is then straightforward to prove that $U_i \subseteq LFP.F_{\upharpoonright_X}$, for each i with $0 < i \leq n$, and so in particular we find that $s \in U_n \subseteq LFP.F_{\upharpoonright_X}$. This finishes the proof of the implication from left to right in (35). \square

As an almost immediate corollary of this result we obtain the second part of Proposition 7.3.

PROOF OF PROPOSITION 7.3(2). Take an arbitrary formula $\mu p. \varphi \in \mu_C \text{FOE}_1^\infty$, then by definition we have $\varphi \in \mu_C \text{FOE}_1^\infty \cap \text{Con}_p(\mu \text{FOE}_1^\infty)$. But it follows from a routine inductive proof that every formula $\psi \in \mu_C \text{FOE}_1^\infty \cap \text{Con}_Q(\mu \text{FOE}_1^\infty)$ is continuous in each variable in Q . Thus φ is continuous in p , and so the result is immediate by Theorem 7.9. \square

7.3. Fixpoints of noetherian maps

We will now see how to prove Proposition 7.3(1), which is the key result that we need to embed alternation-free μ -calculi such as $\mu_N\text{FOE}_1$ and $\mu_N\text{ML}$ into noetherian second-order logic. Perhaps suprisingly, this case is slightly more subtle than the characterisation of fixpoints of continuous maps.

We start with stating some auxiliary definitions and results on monotone functionals, starting with a game-theoretic characterisation of their least fixpoints [Venema 2012].

Definition 7.10. Given a monotone functional $F : \wp(S) \rightarrow \wp(S)$ we define the *unfolding game* \mathcal{U}_F as follows:

- at any position $s \in S$, \exists needs to pick a set X such that $s \in FX$;
- at any position $X \in \wp(S)$, \forall needs to pick an element of X
- all infinite matches are won by \forall .

A positional strategy $f : S \rightarrow \wp(S)$ for \exists in \mathcal{U}_F is *descending* if, for all ordinals α ,

$$s \in F^{\alpha+1}(\emptyset) \text{ implies } f(s) \subseteq F^\alpha(\emptyset). \quad (36)$$

It is not the case that *all* positional winning strategies for \exists in \mathcal{U}_F are descending, but the next result shows that there always is one.

PROPOSITION 7.11. *Let $F : \wp(S) \rightarrow \wp(S)$ be a monotone functional.*

- (1) *For all $s \in S$, $s \in \text{Win}_\exists(\mathcal{U}_F)$ iff $s \in \text{LFP}.F$;*
- (2) *If $s \in \text{LFP}.F$, then \exists has a descending winning strategy in $\mathcal{U}_F@s$.*

PROOF. Point (1) corresponds to [Venema 2012, Theorem 3.14(2)]. For part (2) one can simply take the following strategy. Given $s \in \text{LFP}.F$, let α be the least ordinal such that $s \in F^\alpha(\emptyset)$; it is easy to see that α must be a successor ordinal, say $\alpha = \beta + 1$. Now simply put $f(s) := F^\beta(\emptyset)$. \square

Definition 7.12. Let $F : \wp(S) \rightarrow \wp(S)$ be a monotone functional, let f be a positional winning strategy for \exists in \mathcal{U}_F , and let $r \in S$. Define $T_{f,r} \subseteq S$ to be the set of states in S that are f -reachable in $\mathcal{U}_F@r$. This set has a tree structure induced by the map f itself, where the children of $s \in T_{f,r}$ are given by the set $f(s)$; we will refer to $T_{f,r}$ as the *strategy tree* of f .

Note that a strategy tree $T_{f,r}$ will have no infinite paths, since we define the notion only for a *winning* strategy f .

PROPOSITION 7.13. *Let $F : \wp(S) \rightarrow \wp(S)$ be a monotone functional, let $r \in S$, and let f be a descending winning strategy for \exists in \mathcal{U}_F . Then*

$$r \in \text{LFP}.F \text{ implies } r \in \text{LFP}.F|_{T_{f,r}}. \quad (37)$$

PROOF. Let F, r and f be as in the formulation of the proposition. Assume that $r \in \text{LFP}.F$, then clearly $r \in F^\alpha(\emptyset)$ for some ordinal α ; furthermore, $T_{f,r}$ is defined and clearly we have $r \in T_{f,r}$. Abbreviate $T := T_{f,r}$. It then suffices to show that for all ordinals α we have

$$F^\alpha(\emptyset) \cap T \subseteq (F|_T)^\alpha(\emptyset). \quad (38)$$

We will prove (38) by transfinite induction. The base case, where $\alpha = 0$, and the inductive case where α is a limit ordinal are straightforward, so we focus on the case where α is a successor ordinal, say $\alpha = \beta + 1$. Take an arbitrary state $u \in F^{\beta+1}(\emptyset) \cap T$, then we find $f(u) \subseteq F^\beta(\emptyset)$ by our assumption (36), and $f(u) \subseteq T$ by definition of T . Then the induction hypothesis yields that $f(u) \subseteq (F|_T)^\beta(\emptyset)$, and so we have

$f(u) \subseteq (F_{\uparrow_T})^\beta(\emptyset) \cap T$. But since f is a winning strategy, and u is a winning position for \exists in \mathcal{U}_F by Claim 7.11(i), $f(u)$ is a legitimate move for \exists , and so we have $u \in F(f(u))$. Thus by monotonicity of F we obtain $u \in F((F_{\uparrow_T})^\beta(\emptyset) \cap T)$, and since $u \in T$ by assumption, this means that $u \in (F_{\uparrow_T})^{\beta+1}(\emptyset)$ as required. \square

We now turn to the specific case where we consider the least fixed point of a functional F which is induced by some formula $\varphi(p) \in \mu_N L_1$ on some LTS \mathbb{S} . By Proposition 7.11 and Fact 4.29, \exists has a winning strategy in $\mathcal{E}(\mu p. \varphi(p), \mathbb{S}) @ (\mu p. \varphi(p), s)$ if and only if she has a winning strategy in $\mathcal{U}_F @ s$ too, where $F := \varphi_p^\mathbb{S}$ is the monotone functional defined by $\varphi(p)$. The next Proposition makes this correspondence explicit when $L_1 = \text{FOE}$.

First, we need to introduce some auxiliary concepts and notations. Given a winning strategy f for \exists in $\mathcal{E}(\mu p. \varphi, \mathbb{S}) @ (\mu p. \varphi, s)$, we denote by $B(f)$ the set of all finite f -guided, possibly partial, matches in $\mathcal{E}(\psi, \mathbb{S}) @ (\psi, s)$ in which no position of the form $(\nu q. \psi, r)$ is visited. Let f be a positional winning strategies for \exists in $\mathcal{U}_F @ s$ and f' a winning strategy for her in $\mathcal{E}(\mu p. \varphi, \mathbb{S}) @ (\mu p. \varphi, s)$. We call f and f' *compatible* if each point in $T_{f,s}$ occurs on some path belonging to $B(f')$.

PROPOSITION 7.14. *Let $\varphi(p) \in \mu_N \text{FOE}p$ and $s \in \llbracket \mu p. \varphi \rrbracket^\mathbb{S}$. Then there is a descending winning strategy for \exists in $\mathcal{U}_F @ s$ compatible with a winning strategy for \exists in $\mathcal{E}(\mu p. \varphi, \mathbb{S}) @ (\mu p. \varphi, s)$*

PROOF. Let $F := \varphi_p^\mathbb{S}$ be the monotone functional defined by $\varphi(p)$. From $s \in \llbracket \mu p. \varphi \rrbracket^\mathbb{S}$, we get that $s \in \text{LFP}.F$. Applying Proposition 7.11 to the fact that $s \in \text{LFP}.F$ yields that \exists has a descending winning strategy $f : S \rightarrow \varphi(S)$ in $\mathcal{U}_F @ s$. We define \exists 's strategies f' in $\mathcal{E}(\mu p. \varphi, \mathbb{S}) @ (\mu p. \varphi, s)$, and f^* in $\mathcal{U}_F @ s$ as follows:

- (1) In the evaluation games \mathcal{E} , after the initial automatic move, the position of the match is (φ, s) ; there \exists first plays her positional winning strategy f_s from $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f(s)]) @ (\varphi(p), s)$, and we define her move $f^*(s)$ in the unfolding game \mathcal{U} as the set of all nodes $t \in f(s)$ such that there is a f_s -guided match in $B(f_s)$ whose last position is (p, t) .
- (2) Each time a position (p, t) is reached in the evaluation games \mathcal{E} , distinguish cases:
 - (a) if $t \in \text{Win}_\exists(\mathcal{U}_F)$, then \exists continues with the positional winning strategy f_t from $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f(t)]) @ (\varphi(p), t)$, and we define her move $f^*(t)$ in \mathcal{U} as the set of all nodes $w \in f(t)$ such that there is a f_t -guided match in $B(f_t)$ whose last position (p, w) ;
 - (b) if $t \notin \text{Win}_\exists(\mathcal{U}_F)$, then \exists continues with a random positional strategy and we define $f^*(t) := \emptyset$.
- (3) For any position (p, t) that was not reached in the previous steps, \exists sets $f^*(t) := \emptyset$.

By construction, f' and f^* are compatible. Moreover, $f^*(t) \subseteq f(t)$, for $t \in S$, meaning that f^* is descending. We verify that both f' and f^* are actually winning strategies for \exists in the respective games.

First of all, observe that every position of the form (p, t) reached during a f' -guided match, we have $t \in \text{Win}_\exists(\mathcal{U}_F)$. This can be proved by induction on the number of position of the form (p, t) visited during an f' -guided match. For the inductive step, assume $w \in \text{Win}_\exists(\mathcal{U}_F)$. Hence f_w is winning for \exists in $\mathcal{E}(\varphi, \mathbb{S}[p \mapsto f(w)]) @ (\varphi, w)$. This means that if a position of the form (p, t) is reached, the variable p must be true at t in the model $\mathbb{S}[p \mapsto f(w)]$, meaning that it belongs to the set $f(w)$. By assumption f is a winning strategy for \exists in \mathcal{U}_F , and therefore any element of $f(w)$ is again a member of the set $\text{Win}_\exists(\mathcal{U}_F)$.

Finally, let π be an arbitrary f' -guided match of $\mathcal{E}(\varphi, \mathbb{S}[p \mapsto f(w)]) @ (\varphi, w)$. We verify that π is winning for \exists . First observe that since f is winning for her in $\mathcal{U}_F @ s$, the

fixpoint variable p is unfolded only finitely many times during π . Let (p, t) be the last basic position in π where p occurs. Then from now on f' and f_t coincide, yielding that the match is winning for \exists .

We finally verify that f^* is winning for \exists in the unfolding game $\mathcal{U}_F@s$. First of all, since f' is winning, $B(f')$ does not contain an infinite ascending chain of f' -guided matches, and thence any f^* -guided match in $\mathcal{U}_F@s$ is finite. It therefore remains to verify that for every f^* -guided match π in $\mathcal{U}_F@s$ such that $\text{last}(\pi)$ is an \exists position, she can always move. We do it by induction on the length of a f^* -guided match. At each step, we use compatibility and thus keep track of the corresponding position in the evaluation game $\mathcal{E}(\mu p.\varphi, \mathbb{S})@(\mu p.\varphi, s)$. The initial position for her is $s \in S$. Notice that $f^*(s) = f(s) \cap B(\xi')$ and therefore f' corresponds to f_s on $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f^*(s)])@(\varphi(p), s)$ and it is therefore winning for \exists . In particular, this means that $s \in F(f^*(s))$. Hence, as initial move, \exists is allowed to play $f^*(s)$. Moreover any subsequent choice for \forall is such that there is a winning match $\pi \in B(\xi_s)$ for \exists such that $\text{last}(\pi) = (p, w)$. For the induction step, assume \forall has chosen $t \in f^*(w)$, where $f^*(w) = f(w) \cap B(\xi')$, f' corresponds to the winning strategy f_w on $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f^*(w)])@(\varphi(p), w)$, and there is a winning match $\pi \in B(\xi_w)$ for \exists such that $\text{last}(\pi) = (p, w)$. By construction, f' corresponds to the winning strategy f_t for \exists on $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f(t)])@(\varphi(p), t)$. Because $f^*(t) = f(s) \cap B(\xi')$, f_t is also winning for her in $\mathcal{E}(\varphi(p), \mathbb{S}[p \mapsto f^*(t)])@(\varphi(p), t)$, meaning that $s \in F(f^*(s))$. The move $f^*(t)$ is therefore admissible, and any subsequent choice for \forall is such that there is a winning match $\pi \in B(\xi_t)$ for \exists with $\text{last}(\pi) = (p, w)$. \square

PROOF OF PROPOSITION 7.3(1). Let \mathbb{S} be an LTS and $\varphi(p) \in \mu_N \text{FOE}_1 p$.

The right-to-left direction of (31) being proved by Proposition 7.5, we check the left-to-right direction. We first verify that winning strategies in evaluation games for noetherian fixpoint formulas naturally induce bundles. More precisely:

CLAIM. Let $B^{\mathbb{S}}(f)$ be the projection of $B(f)$ on S , that is the set of all paths in \mathbb{S} that are a projection on S of a f -guided (partial) match in $B(f)$. Then $B^{\mathbb{S}}(f)$ is a bundle.

PROOF OF CLAIM. Assume towards a contradiction that $B^{\mathbb{S}}(f)$ contains an infinite ascending chain $\pi_0 \sqsubset \pi_1 \sqsubset \dots$. Let π be the limit of this chain and consider the set of elements in $B(f)$ that, projected on S , are prefixes of π . By König's Lemma, this set contains an infinite ascending chain whose limit is an infinite f -guided match in $\mathcal{E}(\mu p.\varphi, \mathbb{S})$ which starts at $(\mu p.\varphi, s)$, and of which π is the projection on S . By definition of $B(f)$, the highest bound variable of $\mu p.\varphi$ that gets unravelled infinitely often in ρ is a μ -variable, meaning that the match is winning for \forall , a contradiction. \blacktriangleleft

Assume that $s \in \llbracket \mu p.\varphi \rrbracket^{\mathbb{S}}$, and let $F := \varphi_p^{\mathbb{S}}$ be the monotone functional defined by $\varphi(p)$. By Proposition 7.14, \exists has a winning strategy f' in $\mathcal{E}(\mu p.\varphi, \mathbb{S})@(\mu p.\varphi, s)$ compatible with a descending winning strategy f in $\mathcal{U}_F@s$. By Proposition 7.13, we obtain that $s \in LFP.F|_{T_{f,s}}$. Because of compatibility, every node in $T_{f,s}$ occurs on some path of $B(f')$. From the Claim we know that $B^{\mathbb{S}}(f')$ is a bundle, meaning that $T_{f,s}$ is noetherian as required. \square

8. EXPRESSIVENESS MODULO BISIMILARITY

In this Section we use the tools developed in the previous parts to prove the main results of the paper on expressiveness modulo bisimilarity, viz., Theorem 1.1 stating

$$\mu_N\text{ML} \equiv \text{NMSO}/\leftrightarrow \quad (39)$$

$$\mu_C\text{ML} \equiv \text{WMSO}/\leftrightarrow \quad (40)$$

PROOF OF THEOREM 1.1. The structure of the proof is the same for the statements (39) and (40). In both cases, we will need three steps to establish a link between the modal language on the left hand side of the equation to the bisimulation-invariant fragment of the second-order logic on the right hand side.

The first step is to connect the fragments $\mu_N\text{ML}$ and $\mu_C\text{ML}$ of the modal μ -calculus to, respectively, the weak and the continuous-weak automata for first-order logic without equality. That is, in Theorem 8.1 below we prove the following:

$$\mu_N\text{ML} \equiv \text{Aut}_w(\text{FO}_1) \quad (41)$$

$$\mu_C\text{ML} \equiv \text{Aut}_{wc}(\text{FO}_1) \quad (42)$$

Second, the main observations that we shall make in this section is that

$$\text{Aut}_w(\text{FO}_1) \equiv \text{Aut}_w(\text{FOE}_1)/\leftrightarrow \quad (43)$$

$$\text{Aut}_{wc}(\text{FO}_1) \equiv \text{Aut}_{wc}(\text{FOE}_1^\infty)/\leftrightarrow \quad (44)$$

That is, for (43) we shall see in Theorem 8.4 below that a weak FOE_1 -automaton \mathbb{A} is bisimulation invariant iff it is equivalent to a weak FO_1 -automaton \mathbb{A}^\diamond (effectively obtained from \mathbb{A}); and similarly for (44).

Finally, we use the automata-theoretic characterisations of NMSO and WMSO that we obtained in earlier sections:

$$\text{Aut}_w(\text{FOE}_1) \equiv \text{NMSO} \quad (45)$$

$$\text{Aut}_{wc}(\text{FOE}_1^\infty) \equiv \text{WMSO} \quad (46)$$

Then it is obvious that the equation (39) follows from (41), (43) and (45), while similarly (40) follows from (42), (44) and (46). \square

It is left to prove the equations (41) and (42), and (43) and (44); this we will take care of in the two subsections below.

8.1. Automata for $\mu_N\text{ML}$ and $\mu_C\text{ML}$

In this subsection we consider the automata corresponding to the continuous and the alternation-free μ -calculus. That is, we verify the equations (41) and (42).

THEOREM 8.1.

- (1) *There is an effective construction transforming a formula $\varphi \in \mu\text{ML}$ into an equivalent automaton in $\text{Aut}(\text{FO}_1)$, and vice versa.*
- (2) *There is an effective construction transforming a formula $\varphi \in \mu_N\text{ML}$ into an equivalent automaton in $\text{Aut}_w(\text{FO}_1)$, and vice versa.*
- (3) *There is an effective construction transforming a formula $\varphi \in \mu_C\text{ML}$ into an equivalent automaton in $\text{Aut}_{wc}(\text{FO}_1)$, and vice versa.*

PROOF. In each of these cases the direction from left to right is easy to verify, so we omit details. For the opposite direction, we focus on the hardest case, that is, we will only prove that $\text{Aut}_{wc}(\text{FO}_1) \leq \mu_C\text{ML}$. By Theorem 4.33 it suffices to show

that $\mu_C\text{FO}_1 \leq \mu_C\text{ML}$, and we will in fact provide a direct, inductively defined, truth-preserving translation $(\cdot)^t$ from $\mu_C\text{FO}_1(\mathcal{P})$ to $\mu_C\text{ML}(\mathcal{P})$. Inductively we will ensure that, for every set $Q \subseteq \mathcal{P}$:

$$\varphi \in \text{Con}_Q(\mu\text{FO}_1) \text{ implies } \varphi^t \in \text{Con}_Q(\mu\text{ML}) \quad (47)$$

and that the dual property holds for cocontinuity.

Most of the clauses of the definition of the translation $(\cdot)^t$ are completely standard: for the atomic clause we take $p^t := p$ and $(\neg p)^t := \neg p$, for the boolean connectives we define $(\varphi_0 \vee \varphi_1)^t := \varphi_0^t \vee \varphi_1^t$ and $(\varphi_0 \wedge \varphi_1)^t := \varphi_0^t \wedge \varphi_1^t$, and for the fixpoint operators we take $(\mu p.\varphi)^t := \mu p.\varphi^t$ and $(\nu p.\varphi)^t := \nu p.\varphi^t$ — to see that the latter clauses indeed provide formulas in $\mu_C\text{ML}$ we use (47) and its dual. In all of these cases it is easy to show that (47) holds (or remains true, in the inductive cases).

The only interesting case is where φ is of the form $\bigcirc_\alpha(\varphi_1, \dots, \varphi_n)$. By definition of the language $\mu_C\text{FO}_1$ we may assume that $\alpha(a_1, \dots, a_n) \in \text{Con}_B(\text{FO}_1(A))$, where $A = \{a_1, \dots, a_n\}$ and $B = \{a_1, \dots, a_k\}$, that for each $1 \leq i \leq k$ the formula φ_i belongs to the set $\text{Con}_Q(\mu_C\text{FO}_1)$ and that for each $k+1 \leq j \leq n$ the formula φ_j is Q -free. It follows by the induction hypothesis that $\varphi_l \equiv \varphi_l^t \in \mu_C\text{ML}$ for each l , that $\varphi_i^t \in \text{Con}_Q(\mu\text{ML})$ for each $1 \leq i \leq k$, and that the formula φ_j^t is Q -free for each $k+1 \leq j \leq n$. The key observation is now that by Theorem 4.13 we may without loss of generality assume that α is in *normal form*; that is, a disjunction of formulas of the form $\alpha_{\Sigma, \Pi} = \nabla_{\text{FO}}^+(\Sigma, \Pi)$, where every Σ and Π is a subset of $\wp(A)$, $B \cap \bigcup \Pi = \emptyset$ for every Π , and

$$\nabla_{\text{FO}}^+(\Sigma, \Pi) := \bigwedge_{S \in \Sigma} \exists x \bigwedge_{a \in S} a(x) \wedge \forall x \bigvee_{S \in \Pi} \bigwedge_{a \in S} a(x)$$

We now define

$$\begin{aligned} (\bigcirc_{\alpha_{\Sigma, \Pi}}(\overline{\varphi}))^t &:= \bigwedge_{S \in \Sigma} \diamond \bigwedge_{a_l \in S} \varphi_l^t \wedge \square \bigvee_{S \in \Pi} \bigwedge_{a_j \in S} \varphi_j^t \\ \varphi^t &:= \bigvee (\bigcirc_{\alpha_{\Sigma, \Pi}}(\overline{\varphi}))^t \end{aligned}$$

It is then obvious that φ and φ^t are equivalent, so it remains to verify (47). But this is immediate by the observation that all formulas φ_j^t in the scope of the \square are associated with an a_j belonging to a set $S \subseteq A$ that has an empty intersection with the set B ; that is, each a_j belongs to the set $\{a_{k+1}, \dots, a_n\}$ and so φ_j^t is Q -free. \square

8.2. Bisimulation invariance, one step at a time

In this subsection we will show how the bisimulation invariance results in this paper can be proved by automata-theoretic means. Following Janin & Walukiewicz [Janin and Walukiewicz 1996], we will define a construction that, for $L_1 \in \{\text{FOE}_1, \text{FOE}_1^\infty\}$, transforms an arbitrary L_1 -automaton \mathbb{A} into an FO_1 -automaton \mathbb{A}^\diamond such that \mathbb{A} is bisimulation invariant iff it is equivalent to \mathbb{A}^\diamond . In addition, we will make sure that this transformation preserves both the weakness and the continuity condition. The operation $(\cdot)^\diamond$ is completely determined by the following translation at the one-step level.

Definition 8.2. Recall from Theorem 4.12 that any formula in $\text{FOE}_1^+(A)$ is equivalent to a disjunction of formulas of the form $\nabla_{\text{FOE}}^+(\overline{\mathbf{T}}, \Sigma)$, whereas any formula in $\text{FOE}_1^\infty(A)$ is equivalent to a disjunction of formulas of the form $\nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma)$. Based on these normal forms, for both one-step languages $L_1 = \text{FOE}_1$ and $L_1 = \text{FOE}_1^\infty$,

we define the translation $(\cdot)^\diamond : L_1^+(A) \rightarrow \text{FO}_1^+(A)$ by setting

$$\left(\begin{array}{l} \left(\nabla_{\text{FOE}}^+(\overline{\mathbf{T}}, \Sigma) \right)^\diamond \\ \left(\nabla_{\text{FOE}^\infty}^+(\overline{\mathbf{T}}, \Pi, \Sigma) \right)^\diamond \end{array} \right)^\diamond := \bigwedge_i \exists x_i. \tau_{T_i}^+(x_i) \wedge \forall x. \bigvee_{S \in \Sigma} \tau_S^+(x),$$

and for $\alpha = \bigvee_i \alpha_i$ we define $\alpha^\diamond := \bigvee \alpha_i^\diamond$.

This definition propagates to the level of automata in the obvious way.

Definition 8.3. Let $L_1 \in \{\text{FOE}_1, \text{FOE}_1^\infty\}$ be a one-step language. Given an automaton $\mathbb{A} = \langle A, \Delta, \Omega, a_I \rangle$ in $\text{Aut}(L_1)$, define the automaton $\mathbb{A}^\diamond := \langle A, \Delta^\diamond, \Omega, a_I \rangle$ in $\text{Aut}(\text{FO}_1)$ by putting, for each $(a, c) \in A \times C$:

$$\Delta^\diamond(a, c) := (\Delta(a, c))^\diamond.$$

The main result of this section is the theorem below. For its formulation, recall that \mathbb{S}^ω is the ω -unravelling of the model \mathbb{S} (as defined in the preliminaries). As an immediate corollary of this result, we see that (43) and (44) hold indeed.

THEOREM 8.4. Let $L_1 \in \{\text{FOE}_1, \text{FOE}_1^\infty\}$ be a one-step language and let \mathbb{A} be an L_1 -automaton.

(1) The automata \mathbb{A} and \mathbb{A}^\diamond are related as follows, for every model \mathbb{S} :

$$\mathbb{A}^\diamond \text{ accepts } \mathbb{S} \text{ iff } \mathbb{A} \text{ accepts } \mathbb{S}^\omega. \quad (48)$$

(2) The automaton \mathbb{A} is bisimulation invariant iff $\mathbb{A} \equiv \mathbb{A}^\diamond$.

(3) If $\mathbb{A} \in \text{Aut}_w(L_1)$ then $\mathbb{A}^\diamond \in \text{Aut}_w(\text{FO}_1)$, and if $\mathbb{A} \in \text{Aut}_{wc}(\text{FOE}_1^\infty)$ then $\mathbb{A}^\diamond \in \text{Aut}_{wc}(\text{FO}_1)$.

The remainder of this section is devoted to the proof of Theorem 8.4. The key proposition is the following observation on the one-step translation, that we take from the companion paper [Carreiro et al. 2018].

PROPOSITION 8.5. Let $L_1 \in \{\text{FOE}_1, \text{FOE}_1^\infty\}$. For every one-step model (D, V) and every $\alpha \in L_1^+(A)$ we have

$$(D, V) \models \alpha^\diamond \text{ iff } (D \times \omega, V_\pi) \models \alpha, \quad (49)$$

where V_π is the induced valuation given by $V_\pi(a) := \{(d, k) \mid d \in V(a), k \in \omega\}$.

PROOF OF THEOREM 8.4. The proof of the first part is based on a fairly routine comparison, based on Proposition 8.5, of the acceptance games $\mathcal{A}(\mathbb{A}^\diamond, \mathbb{S})$ and $\mathcal{A}(\mathbb{A}, \mathbb{S}^\omega)$. (In a slightly more general setting, the details of this proof can be found in [Venema 2014].)

For part 2, the direction from right to left is immediate by Theorem 8.1. The opposite direction follows from the following equivalences, where we use the bisimilarity of \mathbb{S} and \mathbb{S}^ω (Fact 2.4):

$$\begin{array}{ll} \mathbb{A} \text{ accepts } \mathbb{S} \text{ iff } \mathbb{A} \text{ accepts } \mathbb{S}^\omega & (\mathbb{A} \text{ bisimulation invariant}) \\ \text{iff } \mathbb{A}^\diamond \text{ accepts } \mathbb{S} & (\text{equivalence (48)}) \end{array}$$

It remains to be checked that the construction $(\cdot)^\diamond$, which has been defined for arbitrary automata in $\text{Aut}(L_1)$, transforms both WMSO-automata and NMSO-automata into automata of the right kind. This can be verified by a straightforward inspection at the one-step level. \square

Remark 8.6. In fact, we are dealing here with an instantiation of a more general phenomenon that is essentially coalgebraic in nature. In [Venema 2014] it is proved that if L_1 and L'_1 are two one-step languages that are connected by a translation

$(\cdot)^\diamond : L'_1 \rightarrow L_1$ satisfying a condition similar to (49), then we find that $Aut(L_1)$ corresponds to the bisimulation-invariant fragment of $Aut(L'_1)$: $Aut(L_1) \equiv Aut(L'_1)/\underline{\leftrightarrow}$. This subsection can be generalized to prove similar results relating $Aut_w(L_1)$ to $Aut_w(L'_1)$, and $Aut_{wc}(L_1)$ to $Aut_{wc}(L'_1)$.
